Theories, Solvers and Static Analysis by Abstract Interpretation

Patrick Cousot, Radhia Cousot, and Laurent Mauborgne

joint work with Laurent Mauborgne

software.imdea.org/people/laurent.mauborgne/

Abstract

- The algebraic/model theoretic design of static analyzers uses abstract domains based on representations of properties and pre-calculated property transformers. It is very efficient. The logical-proof theoretic approach uses SMT solvers/theorem provers and computation of property transformers on-the-fly. It is very expressive. We propose to unify both approaches, so that they can be combined to reach the sweet spot best adapted to a specific application domain in the precision/cost spectrum. We first give a new formalization of the proof theoretic approach in the abstract interpretation framework, introducing a semantics based on multiple interpretations to deal with the soundness of such approaches. Then we describe how to combine them with any other abstract interpretation-based analysis using an iterated reduction to combine abstractions. The key observation is that the Nelson-Oppen procedure which decides satisfiability in a combination of logical theories by exchanging equalities and disequalities computes a reduced product (after the state is enhanced with some new "observations" corresponding to alien terms). By abandoning restrictions ensuring completeness (such as disjointness, convexity, stably-infiniteness, or shininess, etc) we can even broaden the application scope of logical abstractions for static analysis (which is incomplete anyway).

- Joint work with Laurent Mauborgne (IMDEA, Madrid)

Objective

Algebraic abstractions

- Used in abstract interpretation for analysis/verification of finite/infinite systems
- System properties and specifications are abstracted as an algebraic lattice (abstraction-specific encoding of properties)
- Fully automatic: system properties are computed as fixpoints of algebraic transformers
- Abstractions can be combined using the reduced product

Proof theoretic/logical abstractions

- Used in deductive methods
- System properties and specifications are expressed with formulæ of first-order theories (universal encoding of properties)
- Partly automatic: system properties are provided manually by end-users and automatically checked to satisfy verification conditions (with implication defined by the theories)
- Theories can be combined using Nelson-Oppen procedure

Objective

- Show that proof-theoretic/logical abstractions are particular cases of algebraic abstractions
- Show that the Nelson-Oppen procedure is a particular case of the reduced product
- Use this unifying point of view to introduce a new combination of logical and algebraic abstractions

 <-> Convergence of proof theoretic/logical and algebraic property-inference and verification methods

Concrete semantics
In addition, in first-order logic with equality, the interpretation of equality is always that appear in the theorems. The program semantics is usually specified relative to a standard interpretation $\mathfrak{I} \in \mathcal{J}$.

The concrete semantics is given in post-fixpoint form (in case the least fixpoint is not also the least post-fixpoint does not exist, e.g. inexpressibility in Hoare logic).

$\mathcal{R}_3 \triangleq \varphi(\mathcal{R}_3)$

concrete observables

$\mathcal{P}_3 \triangleq \varphi(\mathcal{P}_3)$

concrete properties

$\mathcal{C}_3[\mathcal{P}] \triangleq \text{postfp}^\mathcal{C}\mathcal{F}_3[\mathcal{P}] \in \mathcal{P}_3 \rightarrow \mathcal{P}_3$

concrete semantics of program $\mathcal{P}$

where $\text{postfp}^\mathcal{C}\mathcal{F}_3[\mathcal{P}] \triangleq \{ x \mid f(x) \leq x \}$

Example of program concrete semantics

- **Program**
  
  $p \triangleq x=1; \text{while } \{ x = \text{incr}(x) \}$

- **Arithmetic interpretation**
  
  $\mathfrak{I}$ on integers $\mathcal{J}_V = \mathbb{Z}$

- **Loop invariant**
  
  $\text{lfp}^\mathcal{C}\mathcal{F}_3[\mathcal{P}] = \{ \eta \in \mathcal{R}_3 \mid 0 < \eta(x) \}$

where

$\mathcal{R}_3 \triangleq x \rightarrow \mathcal{J}_V$

concrete environments

$\mathcal{F}_3[\mathcal{P}](X) \triangleq \{ \eta \in \mathcal{R}_3 \mid \eta(x) = 1 \cup [\eta[x \leftarrow \eta(x) + 1] \mid \eta \in X \}$

- **The strongest invariant** is
  
  $\text{lfp}^\mathcal{C}\mathcal{F}_3[\mathcal{P}] = \bigcap \text{postfp}^\mathcal{C}\mathcal{F}_3[\mathcal{P}]$

- **Expressivity**: the lfp may not be expressible in the abstract in which case we use the set of possible invariants

$\mathcal{C}_3[\mathcal{P}] \triangleq \text{postfp}^\mathcal{C}\mathcal{F}_3[\mathcal{P}]$
Concrete domains

- The **standard semantics** describes computations of a system formalized by elements of a domain of observables \( P_\varnothing \) (e.g. set of traces, states, etc).
- The **properties** \( P_\varnothing = \varnothing(P_\varnothing) \) (a property is the set of elements with that property) form a complete lattice \( \langle P_\varnothing, \subseteq, \emptyset, P_\varnothing, \cup, \cap \rangle \).
- The **concrete semantics** \( C_\varnothing = \text{postfp}^{\varsigma} F_\varnothing \) defines the system properties of interest for the verification.
- The **transformer** \( F_\varnothing \) is defined in terms of primitives, e.g.

\[
\begin{align*}
\mathcal{I}[x := e]P & \triangleq [\eta(x \leftarrow [e]_\eta) \mid \eta \in P]\quad \text{Floyd’s assignment post-condition} \\
\mathcal{P}[\varphi]P & \triangleq [\eta \in P \mid [\varphi]_\eta \equiv \text{true}]\quad \text{test}
\end{align*}
\]

Why using post-fixpoints is more general than using the least fixpoint?

- The least fixpoint may not exist (inexpressive logic) while post-fixpoints do exist (invariants).
- When the least fixpoint does exist, there is a bijection with the post-fixpoints (Tarski [1955])

\[
\text{lfp}^{\varsigma} F_\varnothing P = \cap \text{postfp}^{\varsigma} F_\varnothing P \in \text{postfp}^{\varsigma} F_\varnothing P
\]

Concrete property satisfaction

- A program \( P \) satisfies a property \( P \) if and only if

\[
\exists C \in C_\varnothing[P] : C \subseteq P
\]

Multiple concrete interpretations/semantics
About mathematical verification

- A verification relative to a purely mathematical semantics is of poor practical interest.
- Example (Muller’s scheme as analyzed by Kahan)
  \[ x_0 = 11/2.0; \]
  \[ x_1 = 61/11.0; \]
  \[ \text{for } (i=1; i <= 100; i++) \{ \]
  \[ x_2 = 111 - (1130 - 3000/x0) / x1; \]
  \[ x0 = x1; \]
  \[ x1 = x2; \}
- With exact reals, converges to 6 (repulsive fixpoint)
- With any finite precision, converges to 100 (attractive fixpoint)

\[ \Rightarrow \text{Programs have many interpretations } I \in \varphi(\mathcal{I}). \]

Multi-interpreted semantics

- A generalization consists in considering multiple interpretations of logics and programs
- Multi-interpreted properties:
  \[ \mathcal{R}_I \]
  \[ \mathcal{P}_I = \{ I \in \mathcal{I} \wedge \varphi(\mathcal{R}_I) \} \]
  \[ \Rightarrow \varphi((I, \eta) | I \in \mathcal{I} \wedge \eta \in \mathcal{R}_I)^8 \]
- Multi-interpreted transformer:
  \[ F_I[P] \in \mathcal{P}_I \rightarrow \mathcal{P}_I \]
  \[ \preceq \lambda P \in \mathcal{P}_I \rightarrow \lambda I \in \mathcal{I} \cdot F_I[P](P(I)) \]
- Multi-interpreted semantics:
  \[ C_I[P] \in \varphi(\mathcal{P}_I) \]
  \[ \preceq \text{postfp}^\mathcal{P} F_I[P] \]

where \( \preceq \) is the pointwise subset ordering.

Example I of abstraction of a multi-interpreted semantics

- The float operations have 4 possible interpretations depending on the rounding mode (towards \(-\infty, +\infty, 0, \) closest)
- ASTRÉE over-approximates all four semantics

Example II of abstraction of a multi-interpreted semantics

- Ignore some interpretations
  \[ \langle \mathcal{P}_I, \subseteq \rangle \xrightarrow{\gamma_{\mathcal{I} \rightarrow \mathcal{P}_I}} \langle \mathcal{P}_I, \subseteq \rangle \]
  is a Galois connection where
  \[ \alpha_{\mathcal{I} \rightarrow \mathcal{P}_I}(P) \preceq P \land \mathcal{P}_I \]
  \[ \gamma_{\mathcal{I} \rightarrow \mathcal{P}_I}(Q) \preceq \{ (I, \eta) | I \in \mathcal{I} \wedge \eta \in \mathcal{R}_I \land (I \in \mathcal{I} \Rightarrow (I, \eta) \in Q) \} \]

Background on abstract interpretation
### Abstract domains

\[
\langle A, \sqsubseteq, \top, \sqcup, \sqcap, \forall, \Delta, \check{f}, \check{b}, \check{p}, \ldots \rangle
\]

where

\[
\begin{align*}
\overline{P}, \overline{Q}, \ldots & \in A \\
\sqsubseteq & \in A \times A \rightarrow B \\
\bot, \top & \in A \\
\sqcup, \sqcap, \forall, \Delta & \in A \times A \rightarrow A \\
\check{f}, \check{b}, \check{p} & \in (x \times E(x, f, p)) \rightarrow A \rightarrow A
\end{align*}
\]

abstract properties
abstract partial order

\[
\begin{align*}
\sqsubseteq & : \bot \sqsubseteq \overline{P} \sqsubseteq \top \\
\sqcup, \sqcap, \forall, \Delta & : A \times A \rightarrow A
\end{align*}
\]

inifimum, supremum (\(\forall \overline{P} \in A : \bot \sqsubseteq \overline{P} \sqsubseteq \top\))

abstract join, meet, widening, narrowing

\[
\begin{align*}
\check{f} & \in (x \times E(x, f, p)) \rightarrow A \rightarrow A \\
\check{b} & \in (x \times E(x, f, p)) \rightarrow A \rightarrow A \\
\check{p} & \in C(x, f, p) \rightarrow A \rightarrow A
\end{align*}
\]

abstract forward assignment transformer
abstract backward assignment transformer
abstract condition transformer.

### Concretization

\[
\gamma \in A \rightarrow \mathcal{P}_\mathcal{S}
\]

- **Soundness** of abstract domains:
  \[
  (\overline{P} \sqsubseteq \overline{Q}) \Rightarrow (\gamma(\overline{P}) \sqsubseteq \gamma(\overline{Q}))
  \]
  order \(\gamma(\bot) = \emptyset\) infimum
  \[
  (\gamma(\overline{P} \sqcup \overline{Q}) \supseteq (\gamma(\overline{P}) \cup \gamma(\overline{Q}))
  \]
  join \(\gamma(\top) = \mathcal{P}_\mathcal{S}\) supremum

- **Up to an encoding,** the abstraction consists in reasoning on a **subset** of the concrete properties

\[
\gamma[A]\]

where

\[
\gamma[X] = \{\gamma(x) \mid x \in X\}
\]

### Abstract semantics

- **\(A\)** abstract domain
- **\(\sqsubseteq\)** abstract logical implication
- **\(\overline{F}[P] \in A \rightarrow A\)** abstract transformer defined in term of abstract primitives
  \[
  \begin{align*}
  \check{f} & \in (x \times E(x, f, p)) \rightarrow A \rightarrow A \\
  \check{b} & \in (x \times E(x, f, p)) \rightarrow A \rightarrow A \\
  \check{p} & \in C(x, f, p) \rightarrow A \rightarrow A
  \end{align*}
  \]
  abstract forward assignment transformer
  abstract backward assignment transformer
  abstract condition transformer.

- **\(\overline{C}[P] \triangleq \{\text{if} \overline{F}[P]\}\)** least fixpoint semantics, if any
- **\(\overline{C}[P] \triangleq \{\overline{P} \mid \overline{F}[P](\overline{P}) \sqsubseteq \overline{P}\}\)** or else, post-fixpoint abstract semantics

### Soundness and completeness of abstract semantics

- **The abstract semantics is sound iff**
  \[
  \forall \overline{P} \in A : (\exists C \in \overline{C}[P] : \overline{C} \sqsubseteq \overline{P}) \Rightarrow (\exists \overline{C} \in \overline{C}[P] : C \sqsubseteq \gamma(\overline{P}))
  \]
  (any abstract proof of an abstract property can be done in the concrete)

- **The abstract semantics is complete iff**
  \[
  \forall \overline{P} \in A : (\exists C \in \overline{C}[P] : C \sqsubseteq \gamma(\overline{P})) \Rightarrow (\exists \overline{C} \in \overline{C}[P] : \overline{C} \sqsubseteq \overline{P})
  \]
  (any concrete proof of an abstract property can be done in the abstract)
Sufficient soundness condition

- **Theorem 4.4 (Soundness of an abstract post-fixpoint semantics).** If $C[P] \leq \text{postfix} F[P]$, $\overline{C}[P] \leq \text{postfix} F[P]$ and $\gamma : A \rightarrow C$ increasing, then

$$\forall \overline{P} \in A : F[P] \circ \gamma(\overline{P}) \leq \gamma \circ F[P](\overline{P})$$

implies that the abstract semantics is sound.

- This is usually implied by **local conditions** to be checked on the abstract domain

$$\gamma([x := e]P) \supseteq f_\alpha[x := e]\gamma(\overline{P})$$
$$\gamma([b]x := e]P) \supseteq b_\alpha[x := e]\gamma(\overline{P})$$
$$\gamma([p]\varphi]P) \supseteq p_\alpha[\varphi]\gamma(\overline{P})$$

**Compositionality:**

**Theorem 4.3 (Compositionality of abstractions).** The composition of sound (resp. complete) abstractions is sound (resp. complete).

Best abstraction

- If the concretization preserves existing meets then we have a Galois connection

$$\langle P, \sqsubseteq \rangle \xrightarrow{\alpha} \langle A, \sqsubseteq \rangle$$

- If no two abstract properties have the same concretization, the abstraction is surjective

$$\langle P, \sqsubseteq \rangle \xrightarrow{\alpha} \langle A, \sqsubseteq \rangle$$

Beyond bounded verification: Widening

**Definition 4.6 (Widening).** Let $(A, \sqsubseteq)$ be a poset. Then an over-approximating widening $\gamma \in A \times A \mapsto A$ is such that

(a) $\forall x, y \in A : x \sqsubseteq x \bowtie y \land y \sqsubseteq x \bowtie y'$. A terminating widening $\gamma \in A \times A \mapsto A$ is such that

(a) Given any sequence $(x^n, n \geq 0)$, the sequence $y^0 = x^0$, $\ldots$, $y^{n+1} = y^n \bowtie x^n$, $\ldots$ converges (i.e. $\exists \in N : \forall n \geq \ell : y^n = y^\ell$ in which case $y^\ell$ is called the limit of the widened sequence $(x^n, n \geq 0)$).

Traditionally a widening is considered to be both over-approximating and terminating. \(\square\)

Iteration with widening

**Definition 4.7 (Iterates with widening).** The iterates of a transformer $F[P] \in A \mapsto A$ from the infimum $\bot \in A$ with widening $\bowtie \in A \times A$ is defined by recurrence as $F^0 = \bot$, $F^{n+1} = F^n \bowtie F^n$ when $F[P](F^n) \subseteq F^n$ and $F^{n+1} = F^n \bowtie F[P](F^n)$ otherwise. \(\square\)

**Theorem 4.8 (Limit of the iterates with widening).** The iterates in a poset $(A, \sqsubseteq, \bot)$ of a transformer $F[P]$ from the infimum $\bot$ with widening $\bowtie$ converge and their limit is a post-fixpoint of the transformer. \(\square\)
4.1. Abstract Domains

- Each abstract domain \( \langle A, \subseteq, \perp, T, U, \sqcap, V, \Delta, \bar{f}, \bar{b}, \bar{p}, \ldots \rangle \) is implemented separately, by providing a specific computer representation of properties in \( A \), and algorithms for the logical operations \( \subseteq, \perp, T, U, \sqcap, \Delta \), and transformers \( \bar{f}, \bar{b}, \bar{p}, \ldots \).
- Different abstract domains are combined into a reduced product.
- Very efficient but requires skilled experts.

4. BACKGROUND ON ABSTRACT INTERPRETATION

- Systematic abstractions of the multi-interpreted semantics: morphisms for union and intersection and so are increasing for the subset ordering.
- In general, it is a pre-order then.

Another direction for abstraction is to keep the context of interpretations and forget about the proper.

The natural ordering to express abstraction or precision on multi-interpreted semantics is the partial application of a function to a subset of its arguments:

- Syntax
  \[
  \Psi \in \mathcal{F}(\bar{x}, \bar{f}, \bar{p}) \quad \Psi ::= a \mid \neg \Psi \mid \Psi \land \exists x : \Psi
  \]
  a distinguished predicate \( = (t_1, t_2) \) which we write \( t_1 \equiv t_2 \).

- Free variables \( \bar{x} \phi \)

- Satisfaction
  \[
  I \models_\eta \Psi,
  \]
  interpretation \( I \) and an environment \( \eta \) satisfy a formula \( \Psi \).

- Equality
  \[
  I \models_\eta t_1 \equiv t_2 \triangleq [t_1]_{\eta} = [t_2]_{\eta}
  \]
  where \( =_I \) is the unique reflexive, symmetric, antisymmetric, and transitive relation on \( I \).

Extension to multi-interpretations

- A property is described by a formula for multiple interpretations
  \[
  I \in \wp(\mathfrak{A})
  \]

- Semantics of first-order formulæ
  \[
  \gamma^I_\eta \in \mathcal{F}(\bar{x}, \bar{f}, \bar{p}) \xrightarrow{\gamma} \wp_I
  \gamma^I_\eta(\Psi) \triangleq \{ (I, \eta) \mid I \in I \land I \models_\eta \Psi \}
  \]

- But how are we going to describe sets of interpretations \( I \in \wp(\mathfrak{A}) \)?
Defining multiple interpretations as models of theories

- **Theory**: set $\mathcal{T}$ of theorems (closed sentences without any free variable)
- **Models** of a theory (interpretations making true all theorems of the theory)

$$
\mathcal{M}(\mathcal{T}) = \{ I \in \mathcal{I} \mid \forall \Psi \in \mathcal{T} : \exists \eta : I \models \Psi \} \\
= \{ I \in \mathcal{I} \mid \forall \Psi \in \mathcal{T} : \forall \eta : I \models \Psi \}
$$

Checking satisfiability modulo theory

- **Validity modulo theory**
  $$
  \text{valid}_{\mathcal{T}}(\Psi) \triangleq \forall I \in \mathcal{M}(\mathcal{T}) : \forall \eta : I \models_{\eta} \Psi
  $$

- **Satisfiability modulo theory (SMT)**
  $$
  \text{satisfiable}_{\mathcal{T}}(\Psi) \triangleq \exists I \in \mathcal{M}(\mathcal{T}) : \exists \eta : I \models_{\eta} \Psi
  $$

- **Checking satisfiability** for decidable theories
  $$
  \text{satisfiable}_{\mathcal{T}}(\Psi) \iff \neg (\text{decide}_{T}(\forall \exists \Psi : \neg \Psi)) \quad \text{(when } \mathcal{T} \text{ is decidable and deductive)}
  $$
  $$
  \text{satisfiable}_{\mathcal{T}}(\Psi) \iff (\text{decide}_{T}(\exists \exists \Psi : \Psi)) \quad \text{(when } \mathcal{T} \text{ is decidable and complete)}
  $$

- **Most SMT solvers support only limited forms of quantified formulae**

Classical properties of theories

- **Decidable theories**: $\forall \Psi \in \mathbb{F}(x, f, p) : \text{decide}_{\mathcal{T}}(\Psi) \triangleq (\Psi \in \mathcal{T})$ is computable
- **Deductive theories**: closed by deduction
  $$
  \forall \Psi \in \mathcal{T} : \forall \Psi' \in \mathbb{F}(x, f, p), \text{if } \Psi \Rightarrow \Psi' \text{ implies } \Psi' \in \mathcal{T}
  $$
- **Satisfiable theory**
  $$
  \mathcal{M}(\mathcal{T}) \neq \emptyset
  $$
- **Complete theory**
  for all sentences $\Psi$ in the language of the theory, either $\Psi$ is in the theory or $\neg \Psi$ is in the theory.

Example of abstraction:
Logical abstractions
Logical abstract domains

- \( \langle A, T \rangle : A \in \varphi(\mathbb{F}(x, f, p)) \) abstract properties
- \( T \) theory of \( \mathbb{F}(x, f, p) \)
- Abstract domain \( \langle A, \subseteq, \land, \lor, \neg, \Delta, \overline{t}_a, \overline{b}_a, \overline{p}_a, \ldots \rangle \)
- Logical implication \( (\Psi \subseteq \Psi') \equiv ((\forall \overline{x} \Psi \cup \overline{x} \Psi' : \Psi \Rightarrow \Psi') \in T) \)
- A lattice but in general not complete
- The concretization is
  \[ \gamma^A_T(\Psi) \triangleq \{ \langle I, \eta \rangle \mid I \in \mathfrak{M}(T) \land I \models \eta \Psi \} \]

Logical abstract semantics

- Logical abstract semantics
  \[ \overline{C}_a[p] \triangleq \{ \Psi \mid \overline{F}_a[p](\Psi) \subseteq \Psi \} \]
- The logical abstract transformer \( \overline{F}_a[p] \in A \to A \) is defined in terms of primitives
  - \( \overline{t}_a : (x \times \mathbb{T}(x, f)) \to A \to A \) abstract forward assignment transformer
  - \( \overline{b}_a : (x \times \mathbb{T}(x, f)) \to A \to A \) abstract backward assignment transformer
  - \( \overline{p}_a : \mathbb{L} \to A \to A \) condition abstract transformer

Implementation notes ...

- Universal representation of abstract properties by logical formulæ
- Trivial implementations of logical operations \( \land, \lor, \neg, \Delta \)
- Provers or SMT solvers can be used for the abstract implication, \( \subseteq \)
- Concrete transformers are purely syntactic

\[ \begin{align*}
  f_a & \in (\mathbb{X} \times \mathbb{T}(x, f)) \to \mathbb{F}(x, f, p) \\
  b_a & \in (\mathbb{X} \times \mathbb{T}(x, f)) \to \mathbb{F}(x, f, p) \\
  p_a & \in \mathbb{L}(x, f, p) \to \mathbb{F}(x, f, p) \\
\end{align*} \]

But ...

- So the abstract transformers follow by abstraction
  - \( \overline{t}_a[x := t][\Psi] \triangleq \alpha^T_A(t_a[x := t][\Psi]) \) abstract forward assignment transformer
  - \( \overline{b}_a[x := t][\Psi] \triangleq \alpha^T_A(b_a[x := t][\Psi]) \) abstract backward assignment transformer
  - \( \overline{p}_a[v][\Psi] \triangleq \alpha^T_A(p_a[v][\Psi]) \) abstract transformer for program test of condition

- The abstraction algorithm \( \alpha^T_A \in \mathbb{F}(x, f, p) \to A \) to abstract properties in \( A \) may be non-trivial (e.g. quantifiers elimination)

- A widening \( \bigvee \) is needed to ensure convergence of the fixpoint iterates (or else ask the end-user)
Example I of widening: **thresholds**

- Choose a subset $W$ of $\mathcal{A}$ satisfying the ascending chain condition for $\sqsubseteq$,
- Define $X \triangledown Y$ to be (one of) the strongest $\Psi \in W$ such that $Y \Rightarrow \Psi$

Example II of bounded widening: **Craig interpolation**

- Use Craig interpolation (knowing a bound e.g. the specification)
- Move to thresholds to enforced convergence after $k$ widenings with Craig interpolation

---

**Reduced product**

**Definition of the Reduced product:**

Let $\langle A_i, \sqsubseteq_i \rangle$, $i \in \Delta$, $\Delta$ finite, be abstract domains with increasing concretization $\gamma_i \in A_i \rightarrow ^\Delta \Psi$, where $\check{A} \triangleq \bigwedge_{i \in \Delta} A_i$ is their Cartesian product. Their reduced product is $\langle \check{A}, \sqsubseteq \rangle$ where $\langle \check{P}, \check{Q} \rangle \equiv (\check{\gamma}(\check{P}) = \check{\gamma}(\check{Q}))$ and $\check{\gamma}$ as well as $\sqsubseteq$ are naturally extended to the equivalence classes $[\check{P}]$, $\check{P} \in \check{A}$, $\check{Q}$ by $\check{\gamma}([\check{P}]) = \check{\gamma}(\check{P})$ and $[\check{P}] \sqsubseteq [\check{Q}] \triangleq \exists \check{P}', [\check{P}], [\check{Q}] \triangledown : \check{P}' \sqsubseteq \check{Q}$. 

**In practice, the reduced product may be complex to compute but we can use approximations such as the iterated pairwise reduction of the Cartesian product.**

---

**Cartesian product**

**Definition of the Cartesian product:**

Let $\langle A_i, \sqsubseteq_i \rangle$, $i \in \Delta$, $\Delta$ finite, be abstract domains with increasing concretization $\gamma_i \in A_i \rightarrow ^\Delta \Psi$, where $\check{A} \triangleq \bigwedge_{i \in \Delta} A_i$ is their Cartesian product. Their Cartesian product is $\langle \check{A}, \sqsubseteq \rangle$ where $\langle \check{P}, \check{Q} \rangle \equiv (\check{\gamma}(\check{P}) = \check{\gamma}(\check{Q}))$ and $\check{\gamma}$ as well as $\sqsubseteq$ are naturally extended to the equivalence classes $[\check{P}]$, $\check{P} \in \check{A}$, $\check{Q}$ by $\check{\gamma}([\check{P}]) = \check{\gamma}(\check{P})$ and $[\check{P}] \sqsubseteq [\check{Q}] \triangleq \exists \check{P}', [\check{P}], [\check{Q}] \triangledown : \check{P}' \sqsubseteq \check{Q}$. 

---

Reduction

- Example: intervals x congruences
  \[ \rho( x \in [-1,5] \land x = 2 \text{ mod } 4) = x \in [2,2] \land x = 2 \text{ mod } 0 \]
  are equivalent
- Meaning-preserving reduction:
  Let \( \langle A, \sqsubseteq \rangle \) be a poset which is an abstract domain with concretization \( \gamma \in A \rightarrow C \) where \( \langle C, \sqsubseteq \rangle \) is the concrete domain. A meaning-preserving map is \( \rho \in A \rightarrow A \) such that \( \forall P \in A : \gamma(\rho(P)) = \gamma(P) \). The map is a reduction if and only if it is reductive that is \( \forall P \in A : \rho(P) \sqsubseteq P \). □

Why is reduction important

- Without reduction (signs and parity):
  ```
  \[ \begin{align*}
  \text{if } (x \leq 0) \text{ then} & \quad \text{odd}(x) \\
  \text{if } (x > 0) \text{ then} & \quad \text{odd}(x)
  \end{align*} \]
  ```
- With reduction:
  ```
  \[ \begin{align*}
  \text{if } (x \leq 0) \text{ then} & \quad \text{odd}(x) \\
  \text{if } (x > 0) \text{ then} & \quad \text{odd}(x)
  \end{align*} \]
  ```

Iterated reduction

- Definition of iterated reduction:
  Let \( \langle A, \sqsubseteq \rangle \) be a poset which is an abstract domain with concretization \( \gamma \in A \rightarrow C \) where \( \langle C, \sqsubseteq \rangle \) is the concrete domain and \( \rho \in A \rightarrow A \) be a meaning-preserving reduction.
  The iterates of the reduction are \( \rho^0 = \lambda P. P \), \( \rho^{i+1} = \rho(\rho^i) \) for successor ordinals and \( \rho^i = \bigcap_{\beta < i} \rho^\beta \) for limit ordinals.
  The iterates are well-defined when the greatest lower bounds \( \bigcap (\text{glb}) \) do exist in the poset \( \langle A, \sqsubseteq \rangle \).

Finite versus infinite iterated reduction

- Finite iterations of a meaning preserving reduction are meaning preserving (and more precise)
- Infinite iterations, limits of meaning-preserving reduction, may not be meaning-preserving (although more precise). It is when \( \gamma \) preserves glbs.
Pairwise reduction

- Definition of pairwise reduction

Let \( \{A_i, \subseteq_i\} \) be abstract domains with increasing concretization \( \gamma_i \in A_i \mapsto L \) into the concrete domain \( \langle L, \subseteq \rangle \).

For \( i, j \in \Delta, i \neq j \), let \( \rho_{ij} \in \langle A_i \times A_j, \subseteq_{ij} \rangle \) be pairwise meaning-preserving reductions (so that \( \forall (x, y) \in A_i \times A_j : \rho_{ij}(\langle x, y \rangle) \subseteq_{ij} \langle x, y \rangle \) and \( (\gamma_i \times \gamma_j) \circ \rho_{ij} = (\gamma_i \times \gamma_j)^{\mathcal{L}} \)).

Define the pairwise reductions \( \bar{\rho}_{ij} \in \llangle A, \subseteq \rrangle \mapsto \llangle A, \subseteq \rrangle \) of the Cartesian product as

\[
\bar{\rho}_{ij}((\bar{P}_i, \bar{P}_j)) = \rho_{ij}(\bar{P}_i, \bar{P}_j) \quad \text{in} \quad \bar{P}[i \leftarrow \bar{P}_i][j \leftarrow \bar{P}_j]
\]

where \( \bar{P}[i \leftarrow x][j \leftarrow x] = \bar{P}_j \) when \( i \neq j \).

\[\text{TODO:}\]

\[\text{Refaire la preuve}\]

\[\text{Relire ci-dessous}\]

\[\text{Iterated pairwise reduction}\]

- The iterated pairwise reduction of the Cartesian product is meaning preserving

If the limit \( \bar{\rho}^* \) of the iterated reductions is well defined then the reductions are such that \( \forall \bar{P} \in \bar{A} : \forall n \in \mathbb{N} : \bar{\rho}^n(\bar{P}) \subseteq \bar{\rho}^*(\bar{P}) \subseteq \bar{\rho}_{ij}(\bar{P}) \subseteq \bar{P} \), \( i, j \in \Delta, i \neq j \) and meaning-preserving since \( \bar{\rho}^n(\bar{P}), \bar{\rho}_{ij}(\bar{P}), \bar{P} \in [\bar{P}]_{\mathcal{L}} \).

If, moreover, \( \gamma \) preserves greatest lower bounds then \( \bar{\rho}^*(\bar{P}) \in [\bar{P}]_{\mathcal{L}} \).

Pairwise reduction (cont’d)

Define the iterated pairwise reductions \( \bar{\rho}^n, \bar{\rho}^{\mathcal{L}}, \bar{\rho}^* \in \llangle A, \subseteq \rrangle \mapsto \llangle A, \subseteq \rrangle, n \geq 0 \) of the Cartesian product for

\[
\bar{\rho}^n = \bigcirc_{i,j \in \Delta, \ i \neq j} \bar{\rho}_{ij}
\]

where \( \bigcirc_{i=1}^n f_i \triangleq f_{\pi_1} \circ \ldots \circ f_{\pi_n} \) is the function composition for some arbitrary permutation \( \pi \) of \([1, n]\).

Iterated pairwise reduction

- In general, the iterated pairwise reduction of the Cartesian product is not as precise as the reduced product

- Sufficient conditions do exist for their equivalence
Counter-example

- \( L = \varphi([a, b, c]) \)
- \( A_1 = \{\emptyset, [a], T\} \) where \( T = \{a, b, c\} \)
- \( A_2 = \{\emptyset, [a, b], T\} \)
- \( A_3 = \{\emptyset, [a, c], T\} \)
- \( \langle T, [a, b], [a, c]\rangle/\equiv = \langle [a], [a, b], [a, c]\rangle \)
- \( \bar{\rho}_{ij}^*([T, [a, b], [a, c]]) = \langle T, [a, b], [a, c]\rangle \) for \( \Delta = \{1, 2, 3\}, i, j \in \Delta, i \neq j \)
- \( \bar{\rho}^*([T, [a, b], [a, c]]) = \langle T, [a, b], [a, c]\rangle \) is not a minimal element of \( \langle [T, [a, b], [a, c]\rangle/\equiv \).

Nelson-Oppen combination procedure

The Nelson-Oppen combination procedure

- Prove satisfiability in a combination of theories by exchanging equalities and disequalities
- Example: \( \varphi \triangleq (x = a \lor x = b) \land f(x) \neq f(a) \land f(x) \neq f(b) \)
  - Purify: introduce auxiliary variables to separate alien terms and put in conjunctive form
    \[
    \begin{align*}
    \varphi &\triangleq \varphi_1 \land \varphi_2 \\
    \varphi_1 &\triangleq (x = a \lor x = b) \land y = a \land z = b \\
    \varphi_2 &\triangleq f(x) \neq f(y) \land f(x) \neq f(z)
    \end{align*}
    \]
  
Note: where \( a, b \) and \( f \) are in different theories

- Reduce \( \bar{\rho}(\varphi) \): each theory \( T_i \) determines \( E_{ij} \), a (dis-)junction of conjunctions of variable (dis)equalities implied by \( \varphi_j \) and propagates it in all other components \( \varphi_i \)
  
  \[
  \begin{align*}
  E_{12} &\triangleq (x = y) \lor (x = z) \\
  E_{21} &\triangleq (x \neq y) \land (x \neq z)
  \end{align*}
  \]

- Iterate \( \bar{\rho}^*(\varphi) \): until satisfiability is proved in each theory or stabilization of the iterates
The Nelson-Oppen combination procedure

Under appropriate hypotheses (disjointness of the theory signatures, stably-infinite/shininess, convexity to avoid disjunctions, etc), the Nelson-Oppen procedure:

- Terminates (finitely many possible (dis)equalities)
- Is sound (meaning-preserving)
- Is complete (always succeeds if formula is satisfiable)
- Similar techniques are used in theorem provers

Is completeness of the Nelson-Oppen procedure needed?

- Yes, if you want to win the SMT-COMP competition (*)
- No, for program static analysis/verification

- Verification is undecidable anyway so requiring completeness is useless.
- Therefore these hypotheses (disjointness of the theory signatures, stably-infinite/shininess, convexity, etc) can be lifted, the procedure is then sound and incomplete.
- No change to SMT solvers is needed.

Observables in Abstract Interpretation

- (Relational) abstractions of values \((v_1,\ldots,v_n)\) of program variables \((x_1,\ldots,x_n)\) is often too imprecise.

Example: when analyzing quaternions \((a,b,c,d)\) we need to observe the evolution of \(\sqrt{a^2+b^2+c^2+d^2}\) during execution to get a precise analysis of the normalization.

- An observable is specified as the value of a function \(f\) of the values \((v_1,\ldots,v_n)\) of the program variables \((x_1,\ldots,x_n)\) assigned to a fresh auxiliary variable \(x_o\)

\[x_o \equiv f(v_1,\ldots,v_n)\]

(with a precise abstraction of \(f\))
Purification = Observables in A.I.

- The **purification** phase consists in introducing new observables.
- The program can be purified by introducing auxiliary assignments of pure sub-expressions so that forward/backward transformers of purified formulæ always yield purified formulæ.
- Example (f and a,b are in different theories):
  
  \[ y = f(x) = f(a+1) \land f(x) = f(2^b) \]

  becomes
  
  \[ z = a+1; t = 2^b; y = f(x) = f(z) \land f(x) = f(t) \]

Reduction

- The transfer of a (disjunction of) conjunctions of variable (dis-)equalities is a **pairwise iterated reduction**.
- This can be **incomplete** when the signatures are not disjoint.

Static analysis combining logical and algebraic abstractions

- When checking satisfiability of \( \varphi_1 \land \varphi_2 \land \ldots \land \varphi_n \), the Nelson-Oppen procedure generates (dis-)equalities that can be propagated by \( \rho_{la} \) to reduce the \( P_i, i = 1, \ldots, m \), or
- \( \alpha_i(\varphi_1 \land \varphi_2 \land \ldots \land \varphi_n) \) can be propagated by \( \rho_{la} \) to reduce the \( P_i, i = 1, \ldots, m \).
- The purification to theory \( T_i \) of \( \gamma_i(P_i) \) can be propagated to \( \varphi_i \) by \( \rho_{al} \) in order to reduce it to \( \varphi_i \land \gamma_i(P_i) \) (in \( T_i \)).
Advantages

- No need for completeness hypotheses on theories
- Bidirectional reduction between logical and algebraic abstractions
- No need for end-users to provide inductive invariants (discovered by static analysis)
- Easy interaction with end-user (through logical formulæ)
- Easy introduction of new abstractions on either side

\[ \implies \text{Extensible expressive static analyzers / verifiers} \]

Future work

- Still at a conceptual stage
- More experimental work on a prototype is needed to validate the concept

Conclusion

- Future convergence between logic-based proof-theoretic deductive methods using SMT solvers/theorem provers and algebraic methods using abstract interpretation for infinite-state systems?
- Expressiveness is important
- Efficiency is decisive
- Reproducibility is crucial

Another relation between SAT-solvers and abstract interpretation

DPLL is Abstract Interpretation
Leopold Haller (Oxford University)

Re'sume'/ Abstract:

The DPLL algorithm for deciding propositional satisfiability is a fundamental algorithm with applications in several, diverse areas of computer science. In its modern formulation, it combines intelligent model search, deduction, and lemma generation in an elegant and highly efficient manner. An important question is whether the DPLL algorithm can be generalised to richer classes of problems.

In this talk, I will outline how DPLL can naturally be viewed as an instance of abstract interpretation. The resulting abstract DPLL framework is a strict generalisation of DPLL to significantly richer logics and to non-Boolean domains. The instantiation of this framework with safety properties and abstract domains yields a powerful class of program analysis techniques which perform dynamic, property-driven domain-refinement.

These results have immediate consequences for building program analysis tools. I will present an instantiation of the abstract DPLL framework in the domain of floating point intervals. This instantiation dynamically constructs a trace-partitioning over the base domain that is precise enough to prove complex programs correct, yet coarse enough to enable efficient analysis.
The End
Thank You
