

# Programming Languages

Generics,  
Containers and Iterators

G22.2110  
Summer 2010

# Generic programming

Let's us abstract over types and other non-value entities.

Examples:

- A sorting algorithm has the same structure, regardless of the types being sorted
- Stack primitives have the same semantics, regardless of the objects stored on the stack.

One common use:

- algorithms on containers: updating, iteration, search

Language models:

- **C**: macros (textual substitution) or unsafe casts
- **Ada**: generic units and instantiations
- **C++**, **Java**, **C#**: templates
- **ML**: parametric polymorphism, functors

# Parameterizing software components

Construct	parameter(s) bound to:
array	bounds, element type
subprogram	values (arguments)
Ada generic package	values, types, packages
Ada generic subprogram	values, types
C++ class template	values, types
C++ function template	values, types
Java generic	classes
ML function	values (including other functions)
ML type constructor	types
ML functor	values, types, structures

# Templates in C++

```
template <typename T>
class Vector {
public:
    explicit Vector (size_t);    // constructor
    T& operator[] (size_t);    // subscript operator
    ... // other operations
private:
    ... // a size and a pointer to an array
};

Vector<int> V1(100);            // instantiation
Vector<int> V2;                // use default constructor

typedef Vector<employee> Dept; // named instance
```

# Class and value parameters

```
template <typename T, unsigned int i>
class Buffer {
    T v[i];           // storage for buffer
    unsigned int sz; // total capacity
    unsigned int count; // current contents
public:
    Buffer () : sz(i), count(0) { }
    T read ();
    void write (const T& elem);
};

Buffer<Shape *, 100> picture;
```

# Template hopes for the best

```
template <typename T> class List {
    struct Link { // for a list node
        Link *pre, *succ; // doubly linked
        T val;
        Link (Link *p, Link *s, const T& v)
            : pre(p), succ(s), val(v) { }
    };
    Link *head;
public:
    void print (std::ostream& os) {
        for (Link *p = head; p; p = p->succ)
            // operator<< must exist for T
            // if print will be used.
            os << p->val << "\n";
    }
};
```

# Function templates

Instantiated implicitly at point of call:

```
template <typename T>
void sort (vector<T>&) { ... }

void testit (vector<int>& vi) {
    sort(vi);    // implicit instantiation
                // can also write sort<int>(vi);
}
```

# Functions and function templates

Templates and regular functions overload each other:

```
template <typename T> class Complex {...};

template <typename T> T sqrt (T); // template
template <typename T> Complex<T> sqrt (Complex<T>);
                                // different algorithm
double sqrt (double); // regular function

void testit (complex<double> cd) {
    sqrt(2); // sqrt<int>
    sqrt(2.0); // sqrt (double): regular function
    sqrt(cd); // sqrt<complex<double> >
}
```

# Iterators and containers

- Containers are data structures to manage collections of items
- Typical operations: insert, delete, search, count
- Typical algorithms over collections use:
  - ◆ imperative languages: iterators
  - ◆ functional languages: map, fold

```
interface Iterator<E> {  
    boolean hasNext (); // returns true if there are  
                        // more elements  
    E next (); // returns the next element  
    void remove (); // removes the current element  
                  // from the collection  
};
```

# The Standard Template Library

**STL:** A set of useful data structures and algorithms in C++, mostly to handle collections.

- Sequential containers: `list`, `vector`, `deque`
- Associative containers: `set`, `map`

We can *iterate* over these using (what else?) *iterators*.

Iterators provided (for `vector<T>`):

```
vector<T>::iterator  
vector<T>::const_iterator  
vector<T>::reverse_iterator  
vector<T>::const_reverse_iterator
```

Note: Almost no inheritance used in STL.

# Iterators in C++

For standard collection classes, we have member functions `begin` and `end` that return iterators.

We can do the following with an iterator `p` (subject to restrictions):

<code>*p</code>	“Dereference” it to get the element it points to
<code>++p, p++</code>	Advance it to point to the next element
<code>--p, p--</code>	Retreat it to point to the previous element
<code>p+i</code>	Advance it <code>i</code> times
<code>p-i</code>	Retreat it <code>i</code> times

A sequence is defined by a pair of iterators:

- the first points to the first element in the sequence
- the second points to *one past* the last element in the sequence

There is a wide variety of operations that work on sequences.

# Iterator example

```
#include <vector>
#include <string>
#include <iostream>

int main () {
    using namespace std;
    vector<string> ss(20); // initialize to 20 empty strings
    for (int i = 0; i < 20; i++)
        ss[i] = string(1, 'a'+i); // assign "a", "b", etc.
    vector<string>::iterator loc =
        find(ss.begin(), ss.end(), "d"); // find first "d"
    cout << "found:_" << *loc
         << "_at_position_" << loc - ss.begin()
         << endl;
}
```

# STL algorithms, part 1

STL provides a wide variety of standard “algorithms” on sequences.

Example: finding an element that matches a given condition

```
// Find first 7 in the sequence  
list<int>::iterator p = find(c.begin(), c.end(), 7);
```

---

```
// Find first number less than 7 in the sequence  
bool less_than_7 (int v) {  
    return v < 7;  
}
```

```
list<int>::iterator p = find_if(c.begin(), c.end(),  
                               less_than_7);
```

# STL algorithms, part 2

Example: doing something for each element of a sequence

It is often useful to pass a function *or something that acts like a function*:

```
template <typename T>
class Sum {
    T res;
public:
    Sum (T i = 0) : res(i) { }           // initialize
    void operator() (T x) { res += x; } // accumulate
    T result () const { return res; }   // return sum
};

void f (list<double>& ds) {
    Sum<double> sum;
    sum = for_each(ds.begin(), ds.end(), sum);
    cout << "the sum is " << sum.result() << "\n";
}
```

# Function objects

```
template <typename Arg, typename Res> struct unary_function {  
    typedef Arg argument_type;  
    typedef Res result_type;  
};
```

---

```
struct R { string name; ... };
```

```
class R_name_eq : public unary_function<R, bool> {  
    string s;  
public:  
    explicit R_name_eq (const string& ss) : s(ss) { }  
    bool operator() (const R& r) const { return r.name == s; }  
};
```

```
void f (list<R>& lr) {  
    list<R>::iterator p = find_if(lr.begin(), lr.end(),  
                                R_name_eq("Joe"));  
    ...  
}
```

# Binary function objects

```
template <typename Arg, typename Arg2, typename Res>
struct binary_function {
    typedef Arg first_argument_type;
    typedef Arg2 second_argument_type;
    typedef Res result_type;
};
```

```
template <typename T>
struct less : public binary_function<T,T,bool> {
    bool operator() (const T& x, const T& y) const {
        return x < y;
    }
};
```

# Currying with function objects

```
template <typename BinOp>
class binder2nd
    : public unary_function<typename BinOp::first_argument_type,
                           typename BinOp::result_type> {
protected:
    BinOp op;
    typename BinOp::second_argument_type arg2;
public:
    binder2nd (const BinOp& x,
               const typename BinOp::second_argument_type& v)
        : op(x), arg2(v) { }
    return_type operator() (const argument_type& x) const {
        return op(x, arg2);
    }
};

template <typename BinOp, typename T>
binder2nd<BinOp> bind2nd (const BinOp& op, const T& v) {
    return binder2nd<BinOp> (op, v);
}
```

# Partial application with function objects

```
void f (const list<int>& xs, int limit) {
    list<int>::const_iterator it =
        find_if(xs.begin(), xs.end(),
                bind2nd(less<int>(), limit));
    int num = it != xs.end() ? *it : limit;
    ...
}
```

“Is this readable? ... The notation is logical, but it takes some getting used to.” – Stroustrup, p. 520

Equivalent to the following in ML:

```
fun f xs limit =
  let val optNum = List.find (fn x => x < limit) xs
      val num = Option.getOpt (optNum, limit)
  in   ...
  end
```

# C++ templates are Turing complete

Templates in C++ allow for arbitrary computation to be done *at compile time!*

```
template <int N> struct Factorial {
    enum { V = N * Factorial<N-1>::V };
};

template <> struct Factorial<1> {
    enum { V = 1 };
};

void f () {
    const int fact12 = Factorial<12>::V;
    cout << fact12 << endl;    // 479001600
}
```

# Generics in Java

Only class parameters

Implementation by *type erasure*: all instances share the same code

```
interface Collection <E> {  
    public void add (E x);  
    public Iterator<E> iterator ();  
}
```

`Collection <Thing>` is a parametrized type

`Collection` (by itself) is a raw type!

# Generic methods in Java

```
class Collection <A extends Comparable<A>> {  
    public A max () {  
        Iterator<A> xi = this.iterator();  
        A biggest = xi.next();  
        while (xi.hasNext()) {  
            A x = xi.next();  
            if (biggest.compareTo(x) < 0)  
                biggest = x;  
        }  
        return biggest;  
    }  
    ...  
}
```

Why functors, when we have parametric polymorphic functions and type constructors (e.g., containers)?

- Functors can take *structures* as arguments. This is not possible with functions or type constructors.
- Sometimes a type needs to be parameterized on a *value*. This is not possible with type constructors.

# Example functor: the signature

```
signature SET =  
sig  
  type elem  
  type set  
  
  val empty : set  
  val singleton : elem -> set  
  val member : elem * set -> bool  
  val union : set * set -> set  
  ...  
end
```

# Example functor: the implementation

```
functor SetFn (type elem
              val compare : elem * elem -> order) : SET =
structure
  type elem = elem
  datatype set = EMPTY
              | SINGLE of elem
              | PAIR of set * set

  val empty = EMPTY
  val singleton = SINGLE

  fun member (e, EMPTY)           = false
    | member (e, SINGLE e')      = compare (e, e') = EQUAL
    | member (e, PAIR (s1,s2))   = member (e, s1) orelse
                                  member (e, s2)

  ...
end
```

# Example functor: the instantiation

```
structure IntSet =  
  SetFn (type elem = int  
         compare = Int.compare)
```

```
structure StringSet =  
  SetFn (type elem = string  
         compare = String.compare)
```

```
fun cmp (is1, is2) = ...
```

```
structure IntSetSet = SetFn (type elem = IntSet.set  
                             compare = cmp)
```

Compare functor implementation with a polymorphic type: how are element comparisons done?

I/O for integer types.

Identical implementations, but need separate procedures for strong-typing reasons.

```
generic
  type Elem is range <>;    -- any integer type
package Integer_IO is
  procedure Put (Item: Elem);
  ...
end Integer_IO;
```

# A generic Package

```
generic
  type Elem is private; -- parameter
package Stacks is
  type Stack is private;
  procedure Push (X: Elem; On: in out Stack);
  ...
private
  type Cell;           -- linked list
  type Stack is access Cell; -- representation
  type Cell is record
    Val: Elem;
    Next: Ptr;
  end record;
end Stacks;
```

# Instantiations

```
with Stacks;  
procedure Test_Stacks is  
  package Int_Stack  
    is new Stacks (Integer); -- list of integers  
  package Float_Stack  
    is new Stacks (Float);   -- list of floats  
  
  S1: Int_Stack.Stack;      -- stack objects  
  S2: Float_Stack.Stack;  
  
  use Int_Stack, Float_Stack; -- OK, regular packages  
begin  
  Push(15, S1);  
  Push(3.5 * Pi, S2);  
  ...  
end Test_Stacks;
```

# Type parameter restrictions

The syntax is: `type T is ...;`

Restriction	Meaning
<code>private</code>	any type with assignment (non-limited)
<code>limited private</code>	any type (no required operations)
<code>range &lt;&gt;</code>	any integer type (arithmetic operations)
<code>(&lt;&gt;)</code>	any discrete type (enumeration or integer)
<code>digits &lt;&gt;</code>	any floating-point type
<code>delta &lt;&gt;</code>	any fixed-point type

Within the generic, the operations that apply to any type of the class can be used.

The instantiation must use a specific type of the class.

# A generic function

```
generic
  type T is range <>; -- parameter of some integer type
  type Arr is array (Integer range <>) of T;
                    -- parameter is array of those
function Sum_Array (A: Arr) return T;

---

-- Body identical to non-generic version
function Sum_Array (A: Arr) return T is
  Result: T := 0; -- some integer type, so 0 is legal
begin
  for J in A'range loop -- array: 'range available
    Result := Result + A(J); -- integer: "+" available
  end loop;
  return Result;
end;
```

# Instantiating a generic function

```
type Apple is range 1..2**15 - 1;
type Production is array (1..12) of Apple;

type Sick_Days is range 1..5;
type Absences is array (1..52) of Sick_Days;

function Get_Crop is new Sum_Array (Apple ,
                                   Production);
function Lost_Work is new Sum_Array (Sick_Days ,
                                   Absences);
```

# Generic private types

The only available operations are assignment and equality.

```
generic
  type T is private;
procedure Swap (X, Y: in out T);
```

---

```
procedure Swap (X, Y: in out T) is
  Temp: constant T := X;
begin
  X := Y;
  Y := Temp;
end Swap;
```

# Subprogram parameters

A generic sorting routine should apply to any array whose components are comparable, i.e., for which an ordering predicate exists. This class includes more than the numeric types:

```
generic
  type T is                                -- parameter
    private;
  with function "<" (X, Y: T)              -- parameter
    return Boolean;
  type Arr is                               -- parameter
    array (Integer range <>) of T;
  procedure Sort (A: in out Arr);
```

# Supplying subprogram parameters

The actual must have a matching signature, not necessarily the same name:

```
procedure Sort_Up is
  new Sort (Integer, "<", ...);
```

```
procedure Sort_Down is
  new Sort (Integer, ">", ... );
```

```
type Employee is record ... end record;
function Senior (E1, E2: Employee) return Boolean;
function Rank is new Sort (Employee, Senior, ...);
```

# Value parameters

Useful to parameterize containers by size:

```
generic
  type Elem is private;      -- type parameter
  Size: Positive;           -- value parameter
package Queues is
  type Queue is private;
  procedure Enqueue (X: Elem; On: in out Queue);
  procedure Dequeue (X: out Elem; From: in out Queue);
  function Full (Q: Queue) return Boolean;
  function Empty (Q: Queue) return Boolean;
private
  type Contents is array (Natural range <>) of Elem;
  type Queue is record
    Front, Back: Natural;
    C: Contents (0 .. Size);
  end record;
end Queues;
```

# Packages as parameters

```
generic
  type Real is digits <>; -- any floating type
package Generic_Complex_Types is
  -- complex is a record with two real components
  -- package declares all complex operations:
  --   +, -, Re, Im...
  ...
end Generic_Complex_Types;
```

We also want to define a package for elementary functions (`sin`, `cos`, etc.) on complex numbers. This needs the complex operations, which are parameterized by the corresponding real value.

# The instantiation requires an instance of the package parameter

```
with Generic_Complex_Types;  
generic  
  with package Compl is  
    new Generic_Complex_Types (<>);  
package Generic_Complex_Functions is  
  -- trigonometric, exponential,  
  -- hyperbolic functions.  
  ...  
end Generic_Complex_Functions;
```

- Instantiate complex types with long\_float components:

```
package Long_Complex is  
  new Generic_Complex_Type (long_float);
```

- Instantiate complex functions for long\_complex types:

```
package Long_Complex_Functions is  
  new Generic_Complex_Functions (long_complex);
```
