Basic Algorithms, Assignment 10 Solutions

1. Suppose we are given the Minimal Spanning Tree T of a graph G. Now we take an edge $\{x, y\}$ of G which is not in T and reduce its weight $w(x, y)$ to a new value w. Suppose the path from x to y in the Minimal Spanning Tree contains an edge whose weight is bigger than w. Prove that the old Minimal Spanning Tree is no longer the Minimal Spanning Tree.
   `Solution:` We can replace the edge whose weight is bigger than w with the edge $\{x, y\}$ resulting in a lower weight spanning tree.

2. Suppose we ran Kruskal's algorithm on a graph G with n vertices and m edges, no two costs equal. Suppose the the $n - 1$ edges of minimal cost form a tree T.

   (a) Argue that T will be the minimal cost tree.
   `Solution:` From Kruskal's Algorithm we will accept all the edges of T. Then we have a spanning tree so no more edges are accepted.

   (b) How much time will Kruskal's Algorithm take. *Assume* that the edges are *given* to you an array in increasing order of weight. Further, *assume* the Algorithm stops when it finds the MST. Note that the total number m of edges is irrelevant as the algorithm will only look at the first $n - 1$ of them.
   `Solution:` We do n operations $UNION[x, y]$, each takes time $O(\ln n)$ so the total time is $O(n \ln n)$.

   (c) We define Dumb Kruskal. It is Kruskal without the SIZE function. For $UNION[u, v]$ we follow u, v down to their roots x, y as with regular Kruskal but now, if $x \neq y$, we simply reset $\pi[y] = x$. We have the same assumptions on G as above. How long could Dumb Kruskal take. Describe an example where it takes that long. (You can imagine that when the edge u, v is given an adversary puts them in the worst possible order to slow down your algorithm.)
   `Solution:` As $UNION[x, y]$ must take time $O(n)$ (as there are only n vertices) the whole algorithm will take time $O(n^2)$. This can happen. Suppose the edges were, in order, $\{2, 1\}$,$\{3, 1\}$,$\{4, 1\}$, ..., $\{n, 1\}$. For the first edge we make $\pi[1] = 2$. The second edge we follow 1 down to root 2 and set $\pi[2] = 3$. Now for the third

edge we follow 1 to 2 to root 3 and set $\pi[3] = 4$. On the i-th step we are taking time $\sim i$ so it is a $\Theta(n^2)$ running time. tem

(d) Consider Kruskal's Algorithm for MST on a graph with vertex set $\{1, \ldots, n\}$. Assume that the order of the weights of the edges begins $\{1,2\}, \{2,3\}, \{3,4\}, \ldots, \{n-1, n\}$. Assume that when in Kruskal's Algorithm we have a tie $SIZE[x] = SIZE[y]$ we set the smaller of x, y to be the parent of the largest.

i. Show the pattern as the edges are processed. In particular, let $n = 100$ and stop the program when the edge $\{1, 73\}$ has been processed. Give the values of $SIZE[x]$ and $\pi[x]$ for all vertices x.
`Solution:`First we set $\pi[2] = 1$ and $SIZE[1] = 2$. Now for $i = 3, 4, \ldots$ when we process $1, i$ we have $\pi[i] = i$ and $\pi[i-1] = 1$. (In a formal mathematical sense this would be by induction, but its OK just to see the pattern.) So the WHILE loop sends $i - 1$ to ! with $SIZE[1] = i - 1$ and i to itself with $SIZE[i] = 1$ so we set $\pi[i] = 1$ and reset $SIZE[1] = i-1+1 = i$. (That is, the $SIZE[1]$ goes up by one for each iteration.) With $n = 100$ after $\{1, 73\}$ is processed we have $\pi[i] = 1$ for all $1 \leq i \leq 73$ and $SIZE[1] = 73$ and $SIZE[i] = 1$ for $2 \leq i \leq 73$. For the yet untouched i from 74 to 100 we still have the initial values $SIZE[i] = 1, \pi[i] = i$.

ii. Now let n be large and stop the program after $\{1, n\}$ has been processed. Assume the ordering of the weights of the edges was *given* to you, so it took zero time. How long, as an asymptotic function of n, would this program take. (Reasons, please!)
`Solution:`It would be linear $\Theta(n)$ time. At each iteration the WHILE loop is applied zero times for 1 and one time for i so it takes constant time – and we have to run the program through the $n - 1$ edges. `Remark:` This is quite special – in most cases the WHILE loops get long.

3. Here is an alternative approach [1] to Union-Find for Kruskal's Algorithm. You are asked to analyze the time. We have n vertices $1 \cdots n$. Initially each vertex is in its own component. *Assume* the edges have already been ordered by weight. Let E be the number of edges. *As-*

[1] From Aho/Hopcroft/Ullman, Data Structures and Algorithms – though original discovery uncertain.

sume $E = 2V$ (other cases are similar.) Each node is given three attributes:

(a) $LIST[i]$ will be a linked (important!) list of vertices, including i

(b) $NAME[i]$ will be the designated vertex of the component containing i.

(c) $SIZE[i]$ will be, when $NAME[i] = i$, the size of the component containing i. Further, when $NAME[i] = i$, $LIST[i]$ will consist of all the vertices of the component containing i.

The initialization is easy:

(a) $LIST[i] = i$ (the linked list with one item)

(b) $NAME[i] = i$

(c) $SIZE[i] = 1$

Now we consider an edge x, y. If $NAME[x] = NAME[y]$ we reject the edge (x, y lie in the same component) and do nothing. The interesting part is when $NAME[x] \neq NAME[y]$ (which occurs $V - 1 = \Theta(V)$ times) so we need to merge. Reset $x \leftarrow NAME[x]$, $y \leftarrow NAME[y]$. Reorder if necessary so that $SIZE[x] \leq SIZE[y]$. Now

(a) (Rename step) For each z in $LIST[x]$ reset $y \leftarrow NAME[z]$

(b) (size step) Set $SIZE[y] \leftarrow SIZE[y]+SIZE[x]$ (Assume addition takes time $\Theta(1)$.)

(c) (append step) **Append** $LIST[x]$ to $LIST[y]$

Now for the time analysis questions (answers in Θ-land, please) :

(a) What is the total time for cases when x, y lie in the same component?
`Solution:`This occurs $2V - (V - 1) = \Theta(V)$ times and each time we do nothing which takes time $\Theta(1)$ so total time is $\Theta(V)$

(b) What is the total time for the size steps?
`Solution:`This occurs $\Theta(V)$ times, each time the addition, by assumption, takes time $\Theta(1)$ so total time $\Theta(V)$.

(c) What is the total time for the append steps?
`Solution:`This is a key savings as appening one linked list to another takes time $\Theta(1)$ – that is, the length of the lists is immaterial. Again, this occurs $\Theta(V)$ times for a total time of $\Theta(V)$.

(d) Give an upper bound (similar to that in Union-Find) for the number of times a vertex z will be renamed. (Critically, it is the smaller component being renamed!!)
`Solution:` Every time z is renamed $SIZE[NAME[z]]$ goes from $SIZE[x]$ to $SIZE[y] + SIZE[x] \geq 2 \cdot SIZE[x]$. That is, it at least doubles. Hence it can be renamed at most $\lg V$ times.

(e) What is the total time (using O) for the rename steps?
`Solution:` There are V vertices so there is a total of $O(V \lg V)$ renamings.

(f) Putting this all together – what is the total time?
`Solution:` The dominant term is $O(V \lg V)$.
