1. Implementing swtch()

    Per−thread state in thread control block:

        typedef struct tcb {
            unsigned long esp;      /* Stack pointer of thread */
            char *t_stack;          /* Bottom of thread's stack */
            /* ... */
            };

    Machine−dependent thread−switch function:

        void swtch(tcb *current, tcb *next);

    Machine−dependent thread initialization function:

        void thread_init (tcb *t, void (*fn) (void *), void *arg);

    Implementation of swtch(current, next):

        pushl %ebp; movl %esp, %ebp             # Save frame pointer
        pushl %ebx; pushl %esi; pushl %edi      # Save callee−saved regs

        movl 8(%ebp),%edx                       # %edx = current
        movl 12(%ebp),%eax                      # %eax = next
        movl %esp,(%edx)                        # %edx−>esp = %esp
        movl (%eax),%esp                        # %esp = %eax−>esp

        popl %edi; popl %esi; popl %ebx         # Restore callee saved regs
        popl %ebp                               # Restore frame pointer
        ret                                     # Resume execution
```

```
2. Example of compiler output

    foo.c:

        #include <stdio.h>

        int main(int argc, char** argv) {
            printf("hello world\n");
        }

        $ gcc −m32 −fno−builtin −S foo.c

        # −m32 means 32−bit x86 code
        # −S means don't run the assembler

        Here's the output. note that there are two symbolic references:

    foo.s:

                    .file       "foo.c"
                    .section    .rodata
            .LC0:
                    .string     "hello world\n"
                    .text
            .globl main
                    .type       main, @function
            main:
                    pushl       %ebp
                    movl        %esp, %ebp
                    andl        $−16, %esp
                    subl        $16, %esp
                    movl        $.LC0, (%esp)
                    call        printf
```

```
73
74  3. Another example
75
76      main.c:
77          extern float sin();
78          extern int printf(), scanf();
79          float val = 0.0;
80
81          int main(int argc, char** argv) {
82              static float x = 0.0;
83              printf("enter number: ");
84              scanf("%f", &x);
85              val = sin(x);
86              printf("Sine of your value is %f\n", val);
87          }
88
89      C library:
90          int scanf(char* fmt, ...) { ... }
91          int printf(char* fmt, ...) { ...}
92
93      math.c:
94          float sin(float x) {
95              float tmp1, tmp2;
96              static float res = 0.0;
97              static float lastx = 0.0;
98              if (x != lastx) {
99                  lastx = x;
100
101                 /* compute sin */
102             }
103             return res;
104         }
105
106     [thanks to David Mazieres]
```
