Principle of static analysis

- Define the most precise program [property as a fixpoint Ifp \$F\$](#)
- Effectively compute a fixpoint approximation:
 - [iteration-based](#) fixpoint approximation
 - [constraint-based](#) fixpoint approximation

Constraints and Verification, INI, 8 May 2006

— 4 —

© P. Cousot

Iteration-based static analysis

- Effectively overapproximate the iterative fixpoint definition¹:

$$\text{Ifp } F = \bigsqcup_{\lambda \in \mathbb{O}} X^\lambda$$

$$X^0 = \perp$$

$$X^\lambda = \bigsqcup_{\eta < \lambda} F(X^\eta)$$

¹ under Tarski's fixpoint theorem hypotheses

Constraint-based static analysis

- Effectively solve a postfixpoint constraint:

$$\text{Ifp } F = \bigsqcap \{X \mid F(X) \sqsubseteq X\}$$

since $F(X) \sqsubseteq X$ implies $\text{Ifp } F \sqsubseteq X$

- Sometimes, the constraint resolution algorithm is nothing but the iterative computation of $\text{Ifp } F$ ²
- Constraint-based static analysis is the main subject of this talk.

² An example is set-based analysis as shown in Patrick Cousot & Radhia Cousot. *Formal Language, Grammar and Set-Constraint-Based Program Analysis by Abstract Interpretation*. In Conference Record of FPCA '95 ACM Conference on Functional Programming and Computer Architecture, pages 170–181, La Jolla, California, U.S.A., 25–28 June 1995.

Parametric abstraction

- Parametric abstract domain: $X \in \{f(a) \mid a \in \Delta\}$, a is an unknown parameter
- Verification condition: X satisfies $F(X) \sqsubseteq X$ if [and only if] $\exists a \in \Delta : F(f(a)) \sqsubseteq f(a)$ that is $\exists a : C_F(a)$ where $C_F \in \Delta \mapsto \mathbb{B}$ are constraints over the unknown parameter a

Fixpoint versus Constraint-based Approach for Termination Analysis

1. Termination can be expressed in fixpoint form³
2. However we know no effective fixpoint underapproximation method needed to overestimation the termination rank
3. So we consider a constraint-based approach abstracting Floyd's ranking function method

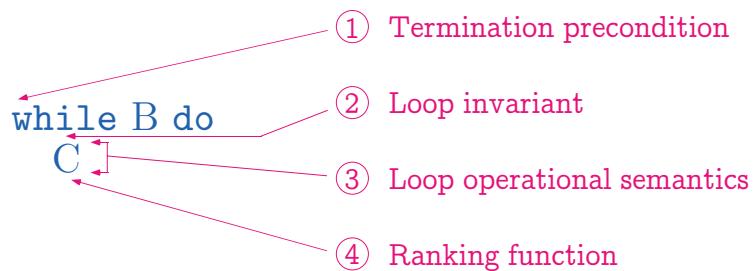

³ See Sect. 11.2 of Patrick Cousot. *Constructive Design of a hierarchy of Semantics of a Transition System by Abstract Interpretation*. *Theoret. Comput. Sci.* 277(1–2):47–103, 2002. © Elsevier Science.

Overview of the Termination Analysis Method

Proving Termination of a Loop

1. Perform an **iterated forward/backward relational static analysis** of the loop with *termination hypothesis* to determine a **necessary proper termination precondition**
2. Assuming the *termination precondition*, perform an **forward relational static analysis** of the loop to determine the **loop invariant**
3. Assuming the loop invariant, perform an **forward relational static analysis** of the loop body to determine the **loop abstract operational semantics**
4. Assuming the loop semantics, use an abstraction of Floyd's **ranking function method** to prove termination of the loop

Proving Termination of a Loop

The main point in this talk is (4).

Arithmetic Mean Example

```
while (x <> y) do
    x := x - 1;
    y := y + 1
od
```

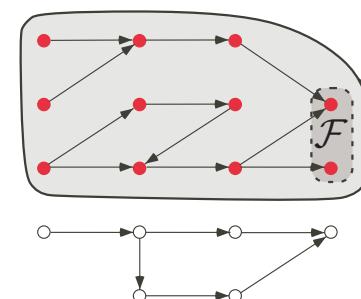

The polyhedral abstraction used for the static analysis of the examples is implemented using Bertrand Jeannet's NewPolka library.

Arithmetic Mean Example

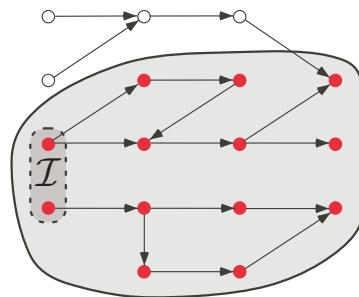

1. Perform an **iterated forward/backward relational static analysis** of the loop with **termination hypothesis** to determine a **necessary proper termination precondition**
2. Assuming the **termination precondition**, perform an **forward relational static analysis** of the loop to determine the **loop invariant**
3. Assuming the **loop invariant**, perform an **forward relational static analysis** of the loop body to determine the **loop abstract operational semantics**
4. Assuming the **loop semantics**, use an abstraction of Floyd's ranking function method to **prove termination of the loop**

Backward/ancestry properties

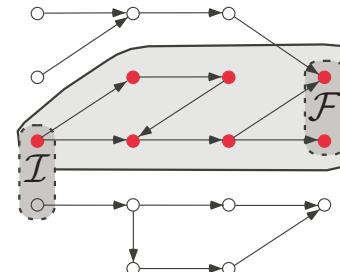

Forward/reachability properties

Example: **partial correctness** (must stay into safe states)

Forward/backward properties

Example: **total correctness** (stay safe while reaching final states)

Principle of the iterated forward/backward iteration-based approximate analysis

– Overapproximate

$$\text{Ifp } F \sqcap \text{Ifp } B$$

by overapproximations of the decreasing sequence

$$\begin{aligned} X^0 &= \top \\ &\dots \\ X^{2n+1} &= \text{Ifp } \lambda Y . X^{2n} \sqcap F(Y) \\ X^{2n+2} &= \text{Ifp } \lambda Y . X^{2n+1} \sqcap B(Y) \\ &\dots \end{aligned}$$

Idea 1

The auxiliary termination counter method

Arithmetic Mean Example: Termination Precondition (1)

```
{x>=y}
  while (x <> y) do
    {x>=y+2}
      x := x - 1;
    {x>=y+1}
      y := y + 1
    {x>=y}
  od
{x=y}
```

Arithmetic Mean Example: Termination Precondition (2)

```
{x=y+2k,x>=y}
  while (x <> y) do
    {x=y+2k,x>=y+2}
      k := k - 1;
    {x=y+2k+2,x>=y+2}
      x := x - 1;
    {x=y+2k+1,x>=y+1}
      y := y + 1
    {x=y+2k,x>=y}
  od
{x=y,k=0}
  assume (k = 0)
{x=y,k=0}
```

Add an auxiliary termination counter to enforce (bounded) termination in the backward analysis!

Arithmetic Mean Example

1. Perform an **iterated forward/backward relational static analysis** of the loop with *termination hypothesis* to determine a **necessary proper termination precondition**
2. Assuming the *termination precondition*, perform an **forward relational static analysis** of the loop to determine the **loop invariant**
3. Assuming the loop invariant, perform an **forward relational static analysis** of the loop body to determine the **loop abstract operational semantics**
4. Assuming the loop semantics, use an abstraction of Floyd's ranking function method to **prove termination of the loop**

Arithmetic Mean Example

1. Perform an **iterated forward/backward relational static analysis** of the loop with *termination hypothesis* to determine a **necessary proper termination precondition**
2. Assuming the *termination precondition*, perform an **forward relational static analysis** of the loop to determine the **loop invariant**
3. Assuming the loop invariant, perform an **forward relational static analysis** of the loop body to determine the **loop abstract operational semantics**
4. Assuming the loop semantics, use an abstraction of Floyd's ranking function method to **prove termination of the loop**

Arithmetic Mean Example: Loop Invariant

```
assume ((x=y+2*k) & (x>=y));
{x=y+2k,x>=y}
while (x <> y) do
  {x=y+2k,x>=y+2}
    k := k - 1;
  {x=y+2k+2,x>=y+2}
    x := x - 1;
  {x=y+2k+1,x>=y+1}
    y := y + 1
  {x=y+2k,x>=y}
od
{k=0,x=y}
```

Arithmetic Mean Example: Body Relational Semantics

Case $x < y$:

```
assume (x=y+2*k)&(x>=y+2);
{x=y+2k,x>=y+2}
assume (x < y);
empty(6)
assume (x0=x)&(y0=y)&(k0=k);
empty(6)
k := k - 1;
x := x - 1;
y := y + 1
empty(6)
```

Case $x > y$:

```
assume (x=y+2*k)&(x>=y+2);
{x=y+2k,x>=y+2}
assume (x > y);
{x=y+2k,x>=y+2}
assume (x0=x)&(y0=y)&(k0=k);
{x=y+2k0,y=y0,x=x0,x=y+2k,
x>=y+2}
k := k - 1;
x := x - 1;
y := y + 1
{x+2=y+2k0,y=y0+1,x+1=x0,
x=y+2k,x>=y}
```

Arithmetic Mean Example

1. Perform an *iterated forward/backward relational static analysis* of the loop with *termination hypothesis* to determine a *necessary proper termination precondition*
2. Assuming the *termination precondition*, perform an *forward relational static analysis* of the loop to determine the *loop invariant*
3. Assuming the *loop invariant*, perform an *forward relational static analysis* of the loop body to determine the *loop abstract operational semantics*
4. Assuming the *loop semantics*, use an *abstraction of Floyd's ranking function method* to prove *termination of the loop*

Problems

- How to get rid of the implication $\Rightarrow ?$
→ *Lagrangian relaxation*
- How to get rid of the universal quantification $\forall ?$
→ *Quantifier elimination/mathematical programming & relaxation*

Floyd's method for termination of while B do C

Given a loop invariant I , find an $\mathbb{R}/\mathbb{Q}/\mathbb{Z}$ -valued unknown *rank function* r such that:

– The rank is *nonnegative*:

$$\forall x_0, x : I(x_0) \wedge [\![B; C]\!](x_0, x) \Rightarrow r(x_0) \geq 0$$

– The rank is *strictly decreasing*:

$$\forall x_0, x : I(x_0) \wedge [\![B; C]\!](x_0, x) \Rightarrow r(x) \leq r(x_0) - \eta$$

$\eta \geq 1$ for \mathbb{Z} , $\eta > 0$ for \mathbb{R}/\mathbb{Q} to avoid Zeno $\frac{1}{2}, \frac{1}{4}, \frac{1}{8} \dots$

Algorithmically interesting cases

- *linear inequalities*
→ linear programming
- *linear matrix inequalities (LMI)/quadratic forms*
→ semidefinite programming
- *semialgebraic sets*
→ polynomial quantifier elimination, or
→ relaxation with semidefinite programming

```

» clear all;
[v0,v] = variables('x','y','k')
% linear inequalities
%      x0 y0 k0
Ai = [ 0 0 0];
%      x  y  k
Ai_ = [ 1 -1 0]; % x0 - y0 >= 0
bi = [0];
[N Mk(:,:,,:)] = linToMk(Ai,Ai_,bi);
% linear equalities
%      x0 y0 k0
Ae = [ 0 0 -2;
       0 -1 0;
       -1 0 0;
       0 0 0];
%      x  y  k
Ae_ = [ 1 -1 0; % x - y - 2*k0 - 2 = 0
        0 1 0; % y - y0 - 1 = 0
        1 0 0; % x - x0 + 1 = 0
        1 -1 -2]; % x - y - 2*k = 0
be = [2; -1; 1; 0];
[M Mk(:,:,N+1:N+M)] = linToMk(Ae,Ae_,be);

```

Arithmetic Mean Example: Ranking Function with Semi-definite Programming Relaxation

Quantifier Elimination

 Constraints and Verification, INI, 8 May 2006

— 31 —

© P. Cousot 

```

» display_Mk(Mk, N, v0, v);
...
+1.x -1.y >= 0
-2.k0 +1.x -1.y +2 = 0
-1.y0 +1.y -1 = 0
-1.x0 +1.x +1 = 0
+1.x -1.y -2.k = 0
...
» [diagnostic,R] = termination(v0, v, Mk, N, 'integer', 'linear');
» disp(diagnostic)
  feasible (bnb)
» intrank(R, v)

r(x,y,k) = +4.k -2

```

 Constraints and Verification, INI, 8 May 2006

— 30 —

© P. Cousot 

- Display the abstract semantics of the loop while B do C
- compute ranking function, if any

Quantifier elimination (Tarski-Seidenberg)

- quantifier elimination for the first-order theory of real closed fields:
 - F is a logical combination of polynomial equations and inequalities in the variables x_1, \dots, x_n
 - Tarski-Seidenberg decision procedure transforms a formula

$$\forall/\exists x_1 : \dots \forall/\exists x_n : F(x_1, \dots, x_n)$$
 into an equivalent quantifier free formula
- cannot be bound by any tower of exponentials [Heintz, Roy, Solerno 89]

 Constraints and Verification, INI, 8 May 2006

— 32 —

© P. Cousot 

Quantifier elimination (Collins)

- cylindrical algebraic decomposition method by Collins
- implemented in MATHEMATICA®
- worst-case time-complexity for real quantifier elimination is “only” doubly exponential in the number of quantifier blocks
- Various optimisations and heuristics can be used⁴

⁴ See e.g. REDLOG <http://www.fmi.uni-passau.de/~redlog/>

Proving Termination by
Parametric Abstraction,
Lagrangian Relaxation and
Semidefinite Programming

Scaling up

However

- does not scale up beyond a few variables!
- too bad!

Idea 2

Express the loop invariant and relational semantics
as numerical positivity constraints

Relational semantics of while B do C od loops

- $x_0 \in \mathbb{R}/\mathbb{Q}/\mathbb{Z}$: values of the loop variables *before* a loop iteration
- $x \in \mathbb{R}/\mathbb{Q}/\mathbb{Z}$: values of the loop variables *after* a loop iteration
- $I(x_0)$: loop invariant, $\llbracket B; C \rrbracket(x_0, x)$: relational semantics of *one iteration of the loop body*

$$I(x_0) \wedge \llbracket B; C \rrbracket(x_0, x) = \bigwedge_{i=1}^N \sigma_i(x_0, x) \geq_i 0 \quad (\geq_i \in \{>, \geq, =\})$$

– not a restriction for numerical programs

Example of linear program (Arithmetic mean)

$$\llbracket A A' \rrbracket[x_0 x]^\top \geq b$$

```
{x=y+2k, x>=y}
while (x <> y) do
    k := k - 1;
    x := x - 1;
    y := y + 1
od
```

$$\begin{aligned}
& +1.x -1.y \geq 0 \\
& -2.k0 +1.x -1.y +2 = 0 \\
& -1.y0 +1.y -1 = 0 \\
& -1.x0 +1.x +1 = 0 \\
& +1.x -1.y -2.k = 0
\end{aligned}$$

$$\left[\begin{array}{ccc|cc} 0 & 0 & 0 & 1 & -1 & 0 \\ 0 & 0 & -2 & 1 & -1 & 0 \\ 0 & -1 & 0 & 0 & 1 & 0 \\ -1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & -1 & -2 \end{array} \right] \left[\begin{array}{c} x_0 \\ y_0 \\ k_0 \\ x \\ y \\ k \end{array} \right] \geq \left[\begin{array}{c} 0 \\ -2 \\ 1 \\ -1 \\ 0 \end{array} \right]$$

Example of quadratic form program (factorial)

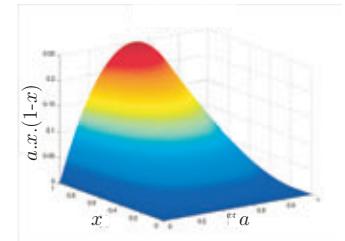

$$\llbracket x x' A [x x']^\top + 2[x x'] q + r \geq 0 \rrbracket$$

```
n := 0;
f := 1;
while (f <= N) do
    n := n + 1;
    f := n * f
od
```

$$\llbracket n_0 f_0 N_0 n f N \rrbracket \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{2} & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -\frac{1}{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} n_0 \\ f_0 \\ N_0 \\ n \\ f \\ N \end{bmatrix} + 2 \llbracket n_0 f_0 N_0 n f N \rrbracket \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ \frac{1}{2} \end{bmatrix} + 0 = 0$$

Example of semialgebraic program (logistic map)

```
eps = 1.0e-9;
while (0 <= a) & (a <= 1 - eps)
    & (eps <= x) & (x <= 1) do
        x := a*x*(1-x)
od
```

Floyd's method for termination of while B do C

Find an $\mathbb{R}/\mathbb{Q}/\mathbb{Z}$ -valued unknown rank function r and $\eta > 0$ such that:

- The rank is *nonnegative*:

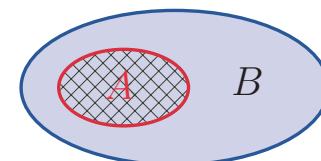

$$\forall x_0, x : \bigwedge_{i=1}^N \sigma_i(x_0, x) \geq_i 0 \Rightarrow r(x_0) \geq 0$$

- The rank is *strictly decreasing*:

$$\forall x_0, x : \bigwedge_{i=1}^N \sigma_i(x_0, x) \geq_i 0 \Rightarrow r(x_0) - r(x) - \eta \geq 0$$

Implication (general case)

$$A \Rightarrow B$$

\Leftrightarrow

$$\forall x \in A : x \in B$$

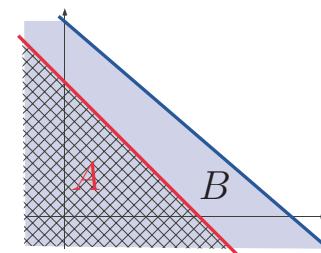

Idea 3

Eliminate the conjunction \wedge and implication \Rightarrow by Lagrangian relaxation

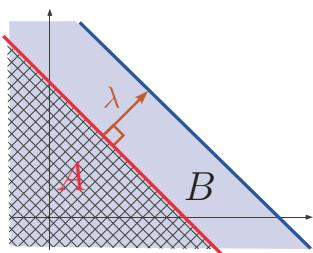

Implication (linear case)

$$\begin{aligned} A \Rightarrow B & \quad (\text{assuming } A \neq \emptyset) \\ \Leftarrow & \text{(soundness)} \\ \Rightarrow & \text{(completeness)} \\ \text{border of } A & \text{ parallel to border of } B \end{aligned}$$

Lagrangian relaxation (linear case)

Lagrangian relaxation, equality constraints

$$\forall x \in \mathbb{V} : \left(\bigwedge_{k=1}^N \sigma_k(x) = 0 \right) \Rightarrow (\sigma_0(x) \geq 0)$$

⇐ soundness (Lagrange)

$$\exists \lambda \in [1, N] \mapsto \mathbb{R}^+ : \forall x \in \mathbb{V} : \sigma_0(x) - \sum_{k=1}^N \lambda_k \sigma_k(x) \geq 0$$

$$\wedge \exists \lambda' \in [1, N] \mapsto \mathbb{R}^+ : \forall x \in \mathbb{V} : \sigma_0(x) + \sum_{k=1}^N \lambda'_k \sigma_k(x) \geq 0$$

$$\Leftrightarrow (\lambda'' = \frac{\lambda' - \lambda}{2})$$

$$\exists \lambda'' \in [1, N] \mapsto \mathbb{R} : \forall x \in \mathbb{V} : \sigma_0(x) - \sum_{k=1}^N \lambda''_k \sigma_k(x) \geq 0$$

Lagrangian relaxation, formally

Let \mathbb{V} be a finite dimensional linear vector space, $N > 0$ and $\forall k \in [0, N] : \sigma_k \in \mathbb{V} \mapsto \mathbb{R}$.

$$\forall x \in \mathbb{V} : \left(\bigwedge_{k=1}^N \sigma_k(x) \geq 0 \right) \Rightarrow (\sigma_0(x) \geq 0)$$

⇐ soundness (Lagrange)

⇒ completeness (lossless)

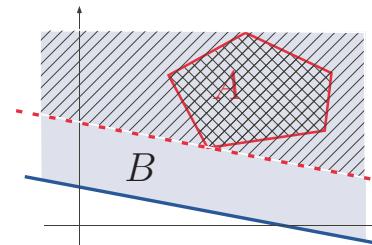

⇏ incompleteness (lossy)

$$\exists \lambda \in [1, N] \mapsto \mathbb{R}^+ : \forall x \in \mathbb{V} : \sigma_0(x) - \sum_{k=1}^N \lambda_k \sigma_k(x) \geq 0$$

relaxation = approximation, λ_i = Lagrange coefficients

Example: affine Farkas' lemma, informally

- An application of Lagrangian relaxation to the case when A is a polyhedron

Example: affine Farkas' lemma, formally

- Formally, if the system $Ax + b \geq 0$ is feasible then

$$\forall x : Ax + b \geq 0 \Rightarrow cx + d \geq 0$$

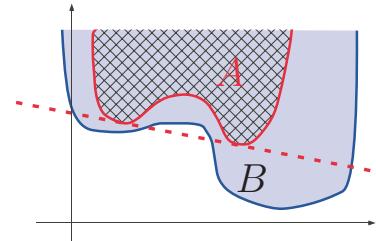

\Leftarrow (soundness, Lagrange)

\Rightarrow (completeness, Farkas)

$$\exists \lambda \geq 0 : \forall x : cx + d - \lambda(Ax + b) \geq 0 .$$

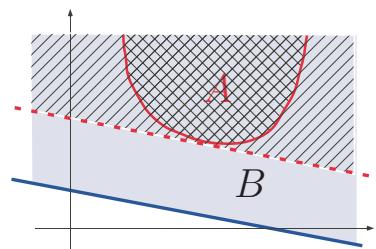

Incompleteness (convex case)

Yakubovich's S-procedure, informally

- An application of Lagrangian relaxation to the case when A is a quadratic form

Yakubovich's S-procedure, completeness cases

- The constraint $\sigma(x) \geq 0$ is *regular* if and only if $\exists \xi \in \mathbb{V} : \sigma(\xi) > 0$.
- The S-procedure is lossless in the case of one regular quadratic constraint:

$$\forall x \in \mathbb{R}^n : x^\top P_1 x + 2q_1^\top x + r_1 \geq 0 \Rightarrow x^\top P_0 x + 2q_0^\top x + r_0 \geq 0$$

\Leftarrow (Lagrange)
 \Rightarrow (Yakubovich)

$$\exists \lambda \geq 0 : \forall x \in \mathbb{R}^n : x^\top \left(\begin{bmatrix} P_0 & q_0 \\ q_0^\top & r_0 \end{bmatrix} - \lambda \begin{bmatrix} P_1 & q_1 \\ q_1^\top & r_1 \end{bmatrix} \right) x \geq 0 .$$

Floyd's method for termination of while B do C

Find an $\mathbb{R}/\mathbb{Q}/\mathbb{Z}$ -valued unknown rank function r which is:

– Nonnegative: $\exists \lambda \in [1, N] \mapsto \mathbb{R}^{+i}$:

$$\forall x_0, x : r(x_0) - \sum_{i=1}^N \lambda_i \sigma_i(x_0, x) \geq 0$$

– Strictly decreasing: $\exists \eta > 0 : \exists \lambda' \in [1, N] \mapsto \mathbb{R}^{+i}$:

$$\forall x_0, x : (r(x_0) - r(x) - \eta) - \sum_{i=1}^N \lambda'_i \sigma_i(x_0, x) \geq 0$$

Idea 4

Parametric abstraction of the ranking function r

Parametric abstraction

– How can we compute the ranking function r ?

→ parametric abstraction:

1. Fix the form r_a of the function r a priori, in term of unknown parameters a
2. Compute the parameters a numerically

– Examples:

$r_a(x) = a \cdot x^\top$	linear
$r_a(x) = a \cdot (x \ 1)^\top$	affine
$r_a(x) = (x \ 1) \cdot a \cdot (x \ 1)^\top$	quadratic

Floyd's method for termination of while B do C

Find $\mathbb{R}/\mathbb{Q}/\mathbb{Z}$ -valued unknown parameters a , such that:

– Nonnegative: $\exists \lambda \in [1, N] \mapsto \mathbb{R}^{+i}$:

$$\forall x_0, x : r_a(x_0) - \sum_{i=1}^N \lambda_i \sigma_i(x_0, x) \geq 0$$

– Strictly decreasing: $\exists \eta > 0 : \exists \lambda' \in [1, N] \mapsto \mathbb{R}^{+i}$:

$$\forall x_0, x : (r_a(x_0) - r_a(x) - \eta) - \sum_{i=1}^N \lambda'_i \sigma_i(x_0, x) \geq 0$$

Idea 5

Eliminate the universal quantification \forall using linear matrix inequalities (LMIs)

Mathematical programming

$$\exists x \in \mathbb{R}^n: \bigwedge_{i=1}^N g_i(x) \geq 0$$

[Minimizing $f(x)$]

feasibility problem : find a solution to the constraints

optimization problem : find a solution, minimizing $f(x)$

Example: Linear programming

$$\exists x \in \mathbb{R}^n: Ax \geq b$$

[Minimizing $c x$]

Feasibility

- feasibility problem: find a solution $s \in \mathbb{R}^n$ to the optimization program, such that $\bigwedge_{i=1}^N g_i(s) \geq 0$, or to determine that the problem is *infeasible*
- feasible set: $\{x \mid \bigwedge_{i=1}^N g_i(x) \geq 0\}$
- a feasibility problem can be converted into the optimization program

$$\min\{-y \in \mathbb{R} \mid \bigwedge_{i=1}^N g_i(x) - y \geq 0\}$$

Semidefinite programming

$$\exists x \in \mathbb{R}^n: M(x) \succcurlyeq 0$$

[Minimizing $c x$]

Where the linear matrix inequality (LMI) is

$$M(x) = M_0 + \sum_{k=1}^n x_k M_k$$

with symmetric matrices ($M_k = M_k^\top$) and the positive semidefiniteness is

$$M(x) \succcurlyeq 0 = \forall X \in \mathbb{R}^N: X^\top M(x) X \geq 0$$

Semidefinite programming, once again

Feasibility is:

$$\exists x \in \mathbb{R}^n : \forall X \in \mathbb{R}^N : X^\top \left(M_0 + \sum_{k=1}^n x_k M_k \right) X \geq 0$$

of the form of the formulæ we are interested in for programs which semantics can be expressed as *LMIs*:

$$\bigwedge_{i=1}^N \sigma_i(x_0, x) \geq_i 0 = \bigwedge_{i=1}^N (x_0 \ x \ 1) M_i (x_0 \ x \ 1)^\top \geq_i 0$$

Floyd's method for termination of while B do C

Find $\mathbb{R}/\mathbb{Q}/\mathbb{Z}$ -valued unknown parameters a , such that:

– Nonnegative: $\exists \lambda \in [1, N] \mapsto \mathbb{R}^{+i} :$

$$\forall x_0, x : r_a(x_0) - \sum_{i=1}^N \lambda_i (x_0 \ x \ 1) M_i (x_0 \ x \ 1)^\top \geq 0$$

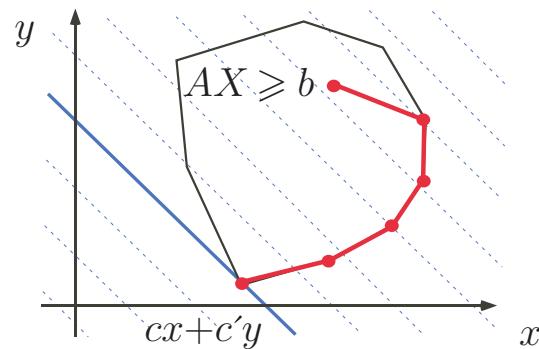

– Strictly decreasing: $\exists \eta > 0 : \exists \lambda' \in [1, N] \mapsto \mathbb{R}^{+i} :$

$$\forall x_0, x : (r_a(x_0) - r_a(x) - \eta) - \sum_{i=1}^N \lambda'_i (x_0 \ x \ 1) M_i (x_0 \ x \ 1)^\top \geq 0$$

Idea 6

Solve the convex constraints by semidefinite programming

The simplex for linear programming

Dantzig 1948, exponential in worst case, good in practice

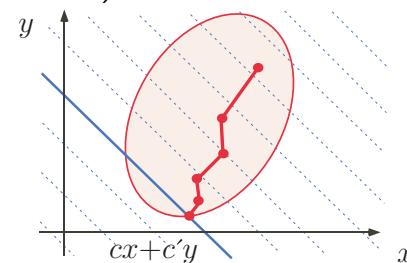

Polynomial Methods for Linear Programming

Ellipsoid method :

- Shor 1970 and Yudin & Nemirovskii 1975,
- polynomial in worst case Khachian 1979,
- but not good in practice

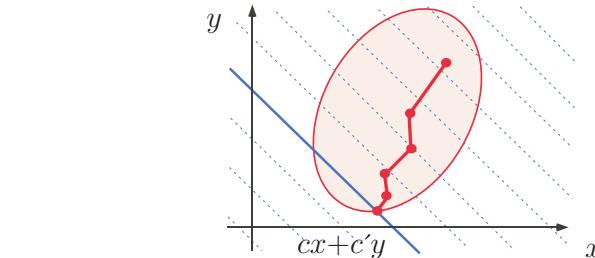

Interior point method :

- Kamarkar 1984,
- polynomial for both average and worst case, and
- good in practice (hundreds of thousands of variables)

Interior point method for semidefinite programming

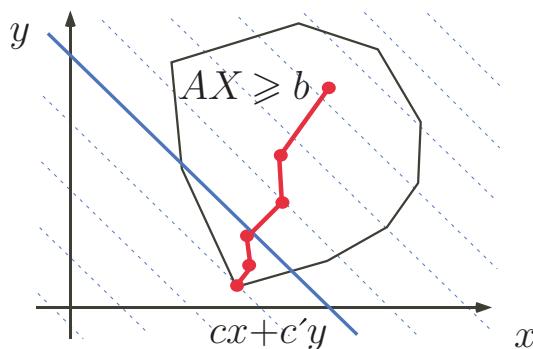

- Nesterov & Nemirovskii 1988, good in practice (thousands of variables)

- Various path strategies e.g. “stay in the middle”

The interior point method

Semidefinite programming solvers

Numerous solvers available under MATLAB®, a.o.:

- [lmiLab](#): P. Gahinet, A. Nemirovskii, A.J. Laub, M. Chilali
- [SdplR](#): S. Burer, R. Monteiro, C. Choi
- [Sdpt3](#): R. Tütüncü, K. Toh, M. Todd
- [SeDuMi](#): J. Sturm
- [bnb](#): J. Löfberg (integer semidefinite programming)

Common interfaces to these solvers, a.o.:

- [Yalmip](#): J. Löfberg

Sometime need some help (feasibility radius, shift,...)

Linear program: termination of Euclidean division

```

       0 0 0];
%      y  q  r
Ai_ = [ 1 0 0; % y - 1 >= 0
        0 1 0; % q - 1 >= 0
        0 0 1]; % r >= 0
bi = [-1; -1; 0];
% linear equalities
%      y0 q0 r0
Ae = [ 0 -1 0; % -q0 + q - 1 = 0
       -1 0 0; % -y0 + y = 0
       0 0 -1]; % -r0 + y + r = 0
%      y  q  r
Ae_ = [ 0 1 0; 1 0 0;
        1 0 1];
be = [-1; 0; 0];

```

 Constraints and Verification, INI, 8 May 2006

Iterated forward/backward polyhedral analysis:

```

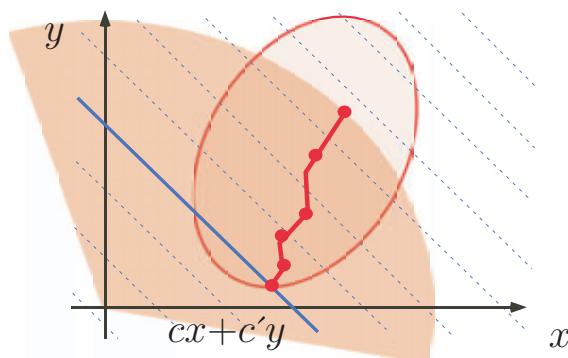

{y>=1}
q := 0;
{q=0,y>=1}
r := x;
{x=r,q=0,y>=1}
while (y <= r) do
{y<=r,q>=0}
r := r - y;
{r>=0,q>=0}
q := q + 1;
{r>=0,q>=1}
od
{q>=0,y>=r+1}

```

Imposing a feasibility radius

 Constraints and Verification, INI, 8 May 2006

— 71 —

© P. Cousot 

```

» [N Mk(:,:,:)]=linToMk(Ai, Ai_, bi);
» [M Mk(:,:,N+1:N+M)]=linToMk(Ae, Ae_, be);
» [v0,v]=variables('y','q','r');
» display_Mk(Mk, N, v0, v);
+1.y -1 >= 0
+1.q -1 >= 0
+1.r >= 0
-1.q0 +1.q -1 = 0
-1.y0 +1.y = 0
-1.r0 +1.y +1.r = 0
» [diagnostic,R] = termination(v0, v, Mk, N, 'integer', 'quadratic');
» disp(diagnostic)
termination (bnb)
» intrank(R, v)
r(y,q,r) = -2.y +2.q +6.r

```

Floyd's proposal $r(x, y, q, r) = x - q$ is more intuitive but requires to discover the nonlinear loop invariant $x = r + qy$.

Quadratic program: termination of factorial

Program:

LMI semantics:

```

n := 0;
f := 1;
while (f <= N) do
  n := n + 1;
  f := n * f
od

```

$$r(n, f, N) = -9.993455e-01.n + 4.346533e-04.f + 2.689218e+02.N + 8.744670e+02$$

 Constraints and Verification, INI, 8 May 2006

Idea 7

Convex abstraction of non-convex constraints

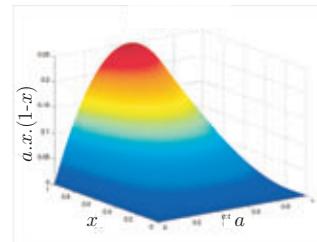

Considering More General Forms of Programs

Semidefinite programming relaxation for polynomial programs

```
eps = 1.0e-9;
while (0 <= a) & (a <= 1 - eps)
    & (eps <= x) & (x <= 1) do
    x := a*x*(1-x)
od
```

Write the verification conditions in polynomial form, use SOS solver to relax in semidefinite programming form.

SOSTool+SeDuMi:

$$r(x) = 1.222356e-13 \cdot x + 1.406392e+00$$

Handling disjunctive loop tests and tests in loop body

- By case analysis
- and “conditional Lagrangian relaxation” (Lagrangian relaxation in each of the cases)

Loop body with tests

```
while (x < y) do
  if (i >= 0) then
    x := x+i+1
  else
    y := y+i
fi
od
```

lmilab:

```
r(i,x,y) = -2.252791e-09.i -4.355697e+07.x +4.355697e+07.y
           +5.502903e+08
```

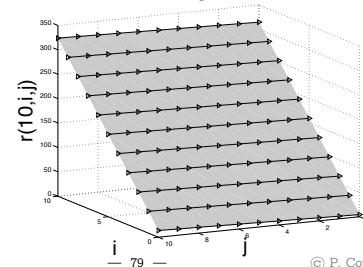

→ case analysis: $\begin{cases} i \geq 0 \\ i < 0 \end{cases}$

sdpllr (with feasibility radius of 1.0e+3):

```
r(n,i,j) = +7.024176e-04.n^2 +4.394909e-05.n.i ...
           -2.809222e-03.n.j +1.533829e-02.n ...
           +1.569773e-03.i^2 +7.077127e-05.i.j ...
           +3.093629e+01.i -7.021870e-04.j^2 ...
           +9.940151e-01.j +4.237694e+00
```

Ranking function

Successive values of
r(n, i, j) for n = 10 on
loop entry

Quadratic termination of linear loop

```
{n>=0}
i := n; j := n;
while (i <> 0) do
  if (j > 0) then
    j := j - 1
  else
    j := n; i := i - 1
  fi
od
```

← termination precondition
determined by iterated forward/backward polyhedral analysis

Handling nested loops

- by induction on the loop depth
- use an iterated forward/backward symbolic analysis to get a necessary termination precondition
- use a forward symbolic symbolic analysis to get the semantics of a loop body
- use Lagrangian relaxation and semidefinite programming to get the ranking function

Example of termination of nested loops: Bubblesort inner loop

```
...
+1.i' -1 >= 0
+1.j' -1 >= 0
+1.n0' -1.i' >= 0
-1.j +1.j' -1 = 0
-1.i +1.i' = 0
-1.n +1.n0' = 0
+1.n0 -1.n0' = 0
+1.n0' -1.n' = 0
...
assume (n0 = n & j >= 0 & i >= 1 & n0 >= i & j <> i);
{n0=n,i>=1,j>=0,n0>=i}
assume (n01 = n0 & n1 = n & i1 = i & j1 = j);
{j=j1,i=i1,n0=n1,n0=n01,n0=n,i>=1,j>=0,n0>=i}
{j=j1+i,i=i1,n0=n1,n0=n01,n0=n,i>=1,j>=1,n0>=i}
j := j + 1
{j=j1+i1,i=i1,n0=n1,n0=n01,n0=n,i>=1,j>=1,n0>=i}

termination (lmilab)
r(n0,n,i,j) = +434297566.n0 +226687644.n -72551842.i
-2.j +2147483647
```

 Constraints and Verification, INI, 8 May 2006

Relaxed Parametric Invariance Proof Method

Floyd's method for invariance

Given a loop precondition P , find an unknown loop invariant I such that:

- The invariant is *initial*:

$$\forall x : P(x) \Rightarrow I(x)$$

- The invariant is *inductive*:

Abstraction

- Express loop semantics as a conjunction of LMI constraints (by relaxation for polynomial semantics)
 - Eliminate the conjunction and implication by Lagrangian relaxation
 - Fix the form of the unknown invariant by parametric abstraction

... we get ...

Floyd's method for numerical programs

Find $\mathbb{R}/\mathbb{Q}/\mathbb{Z}$ -valued unkown parameters a , such that:

- The invariant is *initial*: $\exists \mu \in \mathbb{R}^+$:

$$\forall x : I_{\textcolor{brown}{a}}(x) - \mu.P(x) \geq 0$$

- The invariant is *inductive*: $\exists \lambda \in [0, N] \rightarrow \mathbb{R}^+$:

$$\forall x, x' : I_{\textcolor{brown}{a}}(x') - \lambda_0 \cdot I_{\textcolor{brown}{a}}(x) - \sum_{k=1}^N \lambda_k \cdot \sigma_k(x, x') \geq 0$$

↑ ↑ ↑
 bilinear in λ_0 and a

Idea 8

Solve the bilinear matrix inequality (BMI) by semidefinite programming

Bilinear matrix inequality (BMI) solvers

$$\exists x \in \mathbb{R}^n : \bigwedge_{i=1}^m \left(M_0^i + \sum_{k=1}^n x_k M_k^i + \sum_{k=1}^n \sum_{\ell=1}^n x_k x_{\ell} N_{k\ell}^i \succcurlyeq 0 \right)$$

[Minimizing $x^\top Qx + cx$]

Two solvers available under MATLAB®:

- [PenBMI](#): M. Kočvara, M. Stingl
 - [bmibnb](#): J. Löfberg

Common interfaces to these solvers:

- Yalmip: J. Löfberg

Example: linear invariant

Program:

- Invariant:
 $+2.14678e-12*i -3.12793e-10*j +0.486712 >= 0$
 - Less natural than $i - 2j - 2 \geq 0$
 - Alternative:
 - Determine parameters (*a*) by other methods (e.g. random interpretation)
 - Use BMI solvers to *check* for invariance

Conclusion

Numerical errors

- LMI/BMI solvers do numerical computations with [rounding errors](#), shifts, etc
- ranking function is subject to [numerical errors](#)
- the hard point is to [discover](#) a candidate for the ranking function
- much less difficult, when the ranking function is known, to [re-check](#) for satisfaction (e.g. by static analysis)
- [not very satisfactory for invariance](#) (checking only ???)

Constraint resolution failure

- infeasibility of the constraints does not mean “non termination” or “non invariance” but simply [failure](#)
- inherent to [abstraction](#)!

Related anterior work

- Linear case (Farkas lemma):
 - Invariants: Sankaranarayanan, Spina, Manna (CAV’03, SAS’04, heuristic solver)
 - Termination: Podelski & Rybalchenko (VMCAI’03, Lagrange coefficients eliminated by hand to reduce to linear programming so no disjunctions, no tests, etc)
 - Parallelization & scheduling: Feautrier, easily generalizable to nonlinear case

Related posterior work

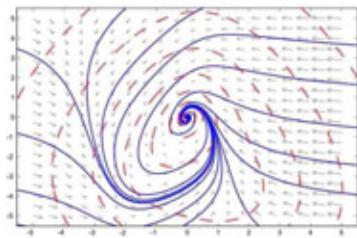

- Termination using Lyapunov functions: Rozbehani, Feron & Megrestki (HSCC 2005)

THE END, THANK YOU

Seminal work

- LMI case, Lyapunov 1890,
“an invariant set of a differential equation is stable in the sense that it attracts all solutions if one can find a function that is bounded from below and decreases along all solutions outside the invariant set”.

ANNEX

- Main steps in a typical soundness/completeness proof
- SOS relaxation principle

Main steps in a typical soundness/completeness proof

$$\exists r : \forall x, x' : \llbracket B; C \rrbracket(x x') \Rightarrow r(x, x') \geq 0$$

$$\iff \exists r : \forall x, x' : \bigwedge_{k=1}^N \sigma_k(x, x') \geq 0 \Rightarrow r(x, x') \geq 0$$

\Leftarrow {Lagrangian relaxation (\Rightarrow if lossless)}

$$\exists r : \exists \lambda \in [1, N] \mapsto \mathbb{R}_* : \forall x, x' \in \mathbb{D}^n : r(x, x') - \sum_{k=1}^N \lambda_k \sigma_k(x, x') \geq 0$$

\Leftarrow {Semantics abstracted in LMI form (\Rightarrow if exact abstraction)}

$$\exists r : \exists \lambda \in [1, N] \mapsto \mathbb{R}_* : \forall x, x' \in \mathbb{D}^n : r(x, x') - \sum_{k=1}^N \lambda_k (x x' 1) M_k (x x' 1)^\top \geq 0$$

\Leftarrow {Choose form of $r(x, x') = (x x' 1) M_0 (x x' 1)^\top$ }

$$\Leftarrow \exists M_0 : \exists \lambda \in [1, N] \mapsto \mathbb{R}_* : \forall x, x' \in \mathbb{D}^n : (x x' 1) M_0 (x x' 1)^\top - \sum_{k=1}^N \lambda_k (x x' 1) M_k (x x' 1)^\top \geq 0$$

$$\iff \exists M_0 : \exists \lambda \in [1, N] \mapsto \mathbb{R}_* : \forall x, x' \in \mathbb{D}^{(n \times 1)} : \begin{bmatrix} x \\ x' \\ 1 \end{bmatrix}^\top \left(M_0 - \sum_{k=1}^N \lambda_k M_k \right) \begin{bmatrix} x \\ x' \\ 1 \end{bmatrix} \geq 0$$

\Leftarrow {if $(x 1) A (x 1)^\top \geq 0$ for all x , this is the same as $(y t) A (y t)^\top \geq 0$ for all y and all $t \neq 0$ (multiply the original inequality by t^2 and call $xt = y$). Since the latter inequality holds true for all x and all $t \neq 0$, by continuity it holds true for all x, t , that is, the original inequality is equivalent to **positive semidefiniteness** of A }

$$\exists M_0 : \exists \lambda \in [1, N] \mapsto \mathbb{R}_* : \left(M_0 - \sum_{k=1}^N \lambda_k M_k \right) \succ 0$$

{LMI solver provides M_0 (and λ)}

SOS Relaxation Principle

- Show $\forall x : p(x) \geq 0$ by $\forall x : p(x) = \sum_{i=1}^k q_i(x)^2$
- Hilbert's 17th problem (sum of squares)
- Undecidable (but for monovariable or low degrees)
- Look for an **approximation (relaxation)** by semidefinite programming

- Instead of quantifying over monomials values x, y , replace the monomial basis z by auxiliary variables X (loosing relationships between values of monomials)
- To find such a $Q \succcurlyeq 0$, check for semidefinite positivity $\exists Q : \forall X : X^\top M(Q)X \geq 0$ i.e. $\exists Q : M(Q) \succeq 0$ with LMI solver
- Implement with **SOSTools** under MATLAB® of Prajna, Papachristodoulou, Seiler and Parrilo
- Nonlinear cost since the monomial basis has size $\binom{n+m}{m}$ for multivariate polynomials of degree n with m variables

General relaxation/approximation idea

- Write the polynomials in quadratic form with monomials as variables: $p(x, y, \dots) = z^\top Qz$ where $Q \succeq 0$ is a semidefinite positive matrix of unknowns and $z = [\dots x^2, xy, y^2, \dots x, y, \dots 1]$ is a monomial basis
- If such a Q does exist then $p(x, y, \dots)$ is a sum of squares⁵
- The equality $p(x, y, \dots) = z^\top Qz$ yields LMI contrains on the unkown Q : $z^\top M(Q)z \succeq 0$

⁵ Since $Q \succeq 0$, Q has a Cholesky decomposition L which is an upper triangular matrix L such that $Q = L^\top L$. It follows that $p(x) = z^\top Qz = z^\top L^\top Lz = (Lz)^\top Lz = [L_{i,:} \cdot z]^\top [L_{i,:} \cdot z] = \sum_i (L_{i,:} \cdot z)^2$ (where \cdot is the vector dot product $x \cdot y = \sum_i x_i y_i$), proving that $p(x)$ is a sum of squares whence $\forall x : p(x) \geq 0$, which eliminates the universal quantification on x .
