1 CS 202, Spring 2024
2 Handout 2 (Class 4)

3
4 The handout is meant to:

- 5 --illustrate how the shell itself uses syscalls
- 6
- 7 --communicate the power of the fork()/exec() separation
- 8
- 9 --give an example of how small, modular pieces (file descriptors, pipes, fork(), exec()) can be combined to achieve complex behavior far beyond what any single application designer could or would have specified at design time. (We will not cover pipes in lecture today.)

1. Pseudocode for a very simple shell

```
17 while (1) {
18     write(1, "$ ", 2);
19     readcommand(command, args); // parse input
20     if ((pid = fork()) == 0) // child?
21         execve(command, args, 0);
22     else if (pid > 0) // parent?
23         wait(0); //wait for child
24     else
25         perror("failed to fork");
26 }
```

2. Now add two features to this simple shell: output redirection and backgrounding

31 By output redirection, we mean, for example:

```
32 $ ls > list.txt
```

33 By backgrounding, we mean, for example:

```
34 $ myprog &
35 $
```

```
37 while (1) {
38     write(1, "$ ", 2);
39     readcommand(command, args); // parse input
40     if ((pid = fork()) == 0) { // child?
41         if (output_redirected) {
42             close(1);
43             open(redirect_file, O_CREAT | O_TRUNC | O_WRONLY, 0666);
44         }
45         // when command runs, fd 1 will refer to the redirected file
46         execve(command, args, 0);
47     } else if (pid > 0) { // parent?
48         if (foreground_process) {
49             wait(0); //wait for child
50         }
51     } else {
52         perror("failed to fork");
53     }
54 }
55 }
```

Page 2/4

3. Another syscall example: pipe()

57
58 The pipe() syscall is used by the shell to implement pipelines, such as
59 \$ ls | sort | head -4
60 We will see this in a moment; for now, here is an example use of
61 pipes.

62
63 // C fragment with simple use of pipes

```
64  
65 int fdarray[2];
66 char buf[512];
67 int n;
68  
69 pipe(fdarray);
70 write(fdarray[1], "hello", 5);
71 n = read(fdarray[0], buf, sizeof(buf));
72 // buf[] now contains 'h', 'e', 'l', 'l', 'o'
```

4. File descriptors are inherited across fork

74
75 // C fragment showing how two processes can communicate over a pipe

```
76  
77 int fdarray[2];
78 char buf[512];
79 int n, pid;
80  
81  
82 pipe(fdarray);
83 pid = fork();
84 if (pid > 0) {
85     write(fdarray[1], "hello", 5);
86 } else {
87     n = read(fdarray[0], buf, sizeof(buf));
88 }
89 }
```

```

90 5. Putting it all together: implementing shell pipelines using
91 fork(), exec(), and pipe().
92
93
94 // Pseudocode for a Unix shell that can run processes in the
95 // background, redirect the output of commands, and implement
96 // two element pipelines, such as "ls | sort"
97
98 void main_loop() {
99
100     while (1) {
101         write(1, "$ ", 2);
102         readcommand(command, args); // parse input
103         if ((pid = fork()) == 0) { // child?
104             if (pipeline_requested) {
105                 handle_pipeline(left_command, right_command)
106             } else {
107                 if (output_redirected) {
108                     close(1);
109                     open(redirect_file, O_CREAT | O_TRUNC | O_WRONLY, 0666);
110                 }
111                 exec(command, args, 0);
112             }
113         } else if (pid > 0) { // parent?
114             if (foreground_process) {
115                 wait(0); // wait for child
116             }
117         } else {
118             perror("failed to fork");
119         }
120     }
121 }
122
123 void handle_pipeline(left_command, right_command) {
124
125     int fdarray[2];
126
127     if (pipe(fdarray) < 0) panic ("error");
128     if ((pid = fork ()) == 0) { // child (left end of pipe)
129
130         dup2 (fdarray[1], 1); // make fd 1 the same as fdarray[1],
131                             // which is the write end of the
132                             // pipe. implies close (1).
133
134         close (fdarray[0]);
135         close (fdarray[1]);
136         parse(command1, args1, left_command);
137         exec (command1, args1, 0);
138     } else if (pid > 0) { // parent (right end of pipe)
139
140         dup2 (fdarray[0], 0); // make fd 0 the same as fdarray[0],
141                             // which is the read end of the pipe.
142                             // implies close (0).
143
144         close (fdarray[0]);
145         close (fdarray[1]);
146         parse(command2, args2, right_command);
147         exec (command2, args2, 0);
148     } else {
149         printf ("Unable to fork\n");
150     }
151 }
152

```

152 6. Commentary

```

153
154
155 Why is this interesting? Because pipelines and output redirection
156 are accomplished by manipulating the child's environment, not by
157 asking a program author to implement a complex set of behaviors.
158 That is, the *identical code* for "ls" can result in printing to the
159 screen ("ls -l"), writing to a file ("ls -l > output.txt"), or
160 getting ls's output formatted by a sorting program ("ls -l | sort").
161
162 This concept is powerful indeed. Consider what would be needed if it
163 weren't for redirection: the author of ls would have had to
164 anticipate every possible output mode and would have had to build in
165 an interface by which the user could specify exactly how the output
166 is treated.
167
168 What makes it work is that the author of ls expressed their
169 code in terms of a file descriptor:
170     write(1, "some output", byte_count);
171 This author does not, and cannot, know what the file descriptor will
172 represent at runtime. Meanwhile, the shell has the opportunity, *in
173 between fork() and exec()*, to arrange to have that file descriptor
174 represent a pipe, a file to write to, the console, etc.

```
